Figure 46.27 shows a memory image of capturing both fields of an interlace input and storing it as a frame image in the memory. Set the start addresses of the memory destination for the captured top-field image in CDAYR and CDACR, and the start addresses of the memory destination for the captured bottom-field image in CDBYR and CDBCR. When storing an interlace image as a frame image in the memory, set the horizontal image size of the memory area in CDWDR with the top-field image and bottom-field image placed next to each other as shown in Figure 46.27. In addition, set the number of captured lines of the field image in the VWDTH bits in CAPWR.

A memory image of folding the horizontal image size of the memory area in Figure 46.27 at CDWDR/2 is shown in Figure 46.28. Setting the registers to form the image in Figure 46.27 enables an interlace image to be stored as a frame image in the memory as shown in Figure 46.28.

### 46.4.9 CEU Register Forcible Control Register (CRCMPR)

CRCMPR forcibly controls switching of the planes of registers with a 2-plane configuration. Setting this register enables direct control of register plane switching.

Do not modify this register during operation. If this register is modified during operation, correct operation cannot be guaranteed. In addition, the IGRW bit (interrupt source) in CETCR is set to B'1.

### 46.4.10 Capture Filter Control Register (CFLCR)

CFLCR sets the scale-down factor for the filter to scale images down.

The CEU has an image scale-down filter which can be used to scale down the captured images before storing them in the memory. Set CFLCR to 0 when not performing scale-down (same size output). If a value other than 0 is set in CFLCR, scale-down is performed. In data fetch mode, set CFLCR to 0.

When handling an interlace source image as a frame image, set CFLCR to 0 not to use the filter.

An image scale-down filter is installed in the CEU, and the captured images can be scaled down and stored in the memory.

**Figure 46.31 Scale-Down of Captured Image**

The formulas for obtaining the MANT (VMANT or HMANT) and FRAC (VFRAC or HFRAC) values from the input pixel count and output pixel count of the filter are shown below. Set the MANT and FRAC bits in order to obtain the desired output pixel count from the number of pixels input to the CEU.

First, calculate preliminary MANT and FRAC values. The parameters needed for calculation are defined as follows:

$$\alpha = MANT \times 4096 + FRAC \quad \dots \text{Formula 1}$$

$$SCL \text{ (scaling factor)} = \frac{4096}{\alpha} \quad \dots \text{Formula 2}$$

Assuming an operator  $\lfloor x \rfloor$  which discards fractions of an integer  $x$ , the MANT and FRAC values can be temporarily set as follows, according to formula 1 and formula 2.

$$MANT = \left\lfloor \frac{1}{SCL} \right\rfloor, \quad FRAC = \left\lfloor 512 \times \left( \frac{1}{SCL} - MANT \right) \right\rfloor \times 8$$

Here, the scaled-down filter output size ( $SIZE_D$ ) can be calculated using the input image size  $S_{in}$  (8-bit interface: half of the CAPWR setting, 16-bit interface: CAPWR setting) in the following formula.

$$SIZE_D = \left\lfloor 1 + \left( \left\lfloor \frac{1}{2} + \frac{S_{in} - 1}{MANT_{pre}} \right\rfloor - 1 \right) \times \frac{MANT_{pre} \times 4096}{\alpha} \right\rfloor \quad \dots \text{Formula 3}$$

$$\left[ \begin{array}{l} MANT_{pre} = 1 \rightarrow (0 \leq MANT < 2) \\ MANT_{pre} = 2 \rightarrow (2 \leq MANT < 4) \\ MANT_{pre} = 4 \rightarrow (4 \leq MANT < 8) \\ MANT_{pre} = 8 \rightarrow (8 \leq MANT) \end{array} \right]$$

The number of output pixels can be obtained by substituting the temporarily calculated MANT, FRAC, and input image size into these formulas. If the calculated number of output pixels is smaller than the number of output pixels used to obtain the preliminary MANT and FRAC values, recalculate with a smaller FRAC ( $\alpha$ ) value, and set the MANT and FRAC values in this register so that a pixel value greater than the desired number of output pixels can be obtained.

Example: Scale down 640 pixels to 480 pixels

$SCL = 480/640 = 3/4$ , and the preliminary settings of  $MANT = 1$ ,  $MANT_{pre} = 1$ , and  $FRAC = H'550$  are made. Substituting these in the following formula results in an output pixel count of 479.

$$SIZE_D = \left\lfloor 1 + \left( \left\lfloor \frac{1}{2} + \frac{S_{in} - 1}{MANT_{pre}} \right\rfloor - 1 \right) \times \frac{MANT_{pre} \times 4096}{\alpha} \right\rfloor \quad \dots \text{Formula 3}$$

Since this output pixel count is smaller than the desired output pixel count of 480, the formula is recalculated with a FRAC value of H'548, a value eight less than the previous time. The obtained result of output pixel count = 480 is equal to the desired output pixel count of 480, so this register is set as  $MANT = 1$  and  $FRAC = H'548$ .

**Table 46.8** Setting Examples for Each Scale-Down Filter Factor

3/4	1352	H'548	1	640	480	480

1/8	0.0	H'0	8	640	80	80
1/16	4088	H'FF8	15	640	40	40

Note: This scale-down filter uses a VGA-size line memory for scale-down. Therefore, when an image larger than the VGA size is input for scale-down, settings must be made so that the output image size is equal to or larger than the SubQCIF size and equal to or smaller than the VGA size. When an image is not scaled down (same size output), this restriction does not apply.

#### 46.4.11 Capture Filter Size Clip Register (CFSZR)

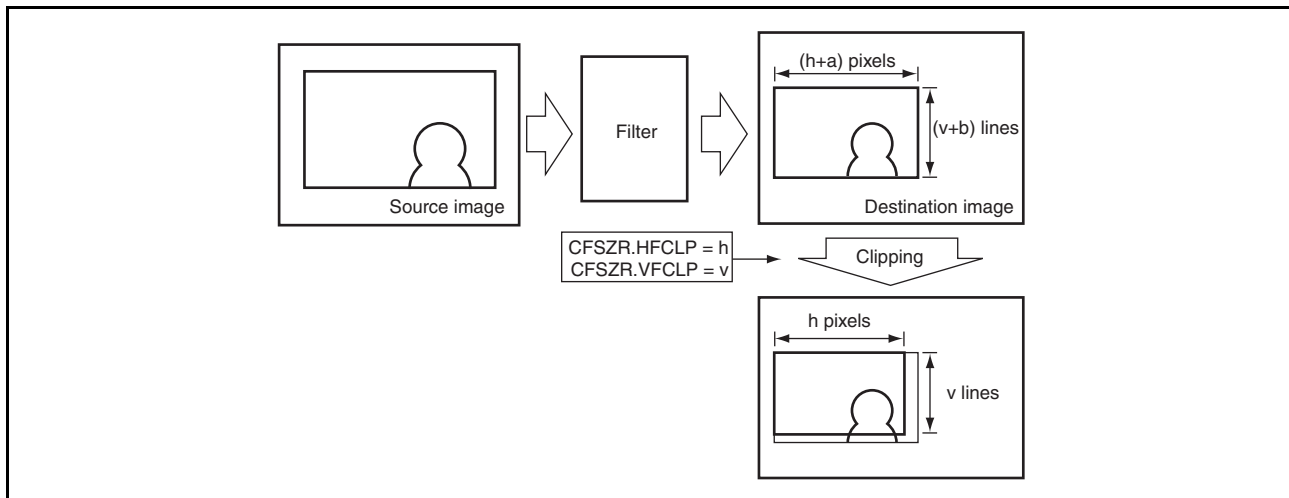

CFSZR sets the clipping size for fine adjustment of the image size output from the filter, and must be set in combination with CFLCR. When clipping the output size of the filter, set the clipping size as a number of pixels, and the setting unit should be four pixels. CFSZR must be set even when scale-down is not performed (same size output).

In data synchronous fetch mode, set CFSZR according to the setting of CAPWR.

31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27 to 18 17, 16	VFCLP[11:2] VFCLP[1:0]	H'000	R/W R	These bits set the vertical clipping value of the filter output size (4-pixel units).
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 2 1, 0	HFCLP[11:2] HFCLP[1:0]	H'000	R/W R	These bits specify the horizontal clipping value of the filter output size (4-pixel units).

The scale-down filter in the CEU may output an odd number of pixels or lines depending on the settings. To adjust the output size of the filter, the CEU clips the destination image by using the number of pixels specified in CFSZR, as shown in Figure 46.32. The clipping size must be specified vertically and horizontally in 4-pixel units.

**Figure 46.32 Clipping of Image Output from Filter**

The pixels to be clipped are counted from the top-left corner of a display. The pixels located to the right of the specified number of pixels or below the specified number of lines are discarded by the clipping function. If the number of pixels specified in CFSZR is larger than that output from the filter, correct operation cannot be guaranteed. To avoid this, the clipping size specified in CFSZR must be equal to or smaller than the number of pixels output from the filter.

Note: In data synchronous fetch mode, the following settings are required. Data cannot be fetched correctly unless the following settings are made.

8-bit interface:  $VFCLP = CAPWR.VWDTH$

$HFCLP = CAPWR.HWDTH/2$

16-bit interface:  $VFCLP = CAPWR.VWDTH$

$HFCLP = CAPWR.HWDTH$

### 46.4.12 Capture Destination Width Register (CDWDR)

CDWDR sets the horizontal image size in the memory area where the captured image is to be output in 4-byte units (4-pixel units).

In data synchronous fetch mode, set CDWDR according to the setting of CAPWR.

This register is not used, during data enable fetch mode.

12 to 2 1, 0	CHDW[12:2] CHDW[1:0]	H'0000	R/W R	These bits specify the horizontal image size in the memory area where the captured image is to be stored (4-byte units). The image data captured by the CEU is stored in the memory. If the right end of the captured image does not match the horizontal image size in the memory area as shown in Figure 46.33, some addresses must be skipped at the right end of the image when storing the captured image. Therefore, the horizontal image size in the memory area where the captured image is to be stored must be set in these bits. The maximum value to be set is 8188 bytes (8188 pixels). In data synchronous fetch mode, set as follows: 8-bit interface: CHDW = CAPWR.HWDTH 16-bit interface: CHDW = CAPWR.HWDTH × 2

### 46.4.13 Capture Data Address Y Register (CDAYR)

CDAYR specifies the address where the luminance (Y) component of the captured data is to be stored in frame image capture or one-field image capture, the address where the luminance (Y) component of the captured top field is to be stored in both-field image capture, and the address where the fetched data is to be stored in data fetch. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. In frame image capture or one-field image capture, set the start address of the memory area where the Y (luminance) component of the captured data is to be stored by CDAYR. In both-field image capture, set the start address of the memory area where the Y (luminance) component of the captured top-field image is to be stored by CDAYR. In data fetch, set the start address of the memory area where data is to be stored by CDAYR.

Because the address must be specified in 32 bits, the address set by CDAYR must be in longword units. As the setting is in 4-pixel units for image capture and 4-byte units for data fetch, the lower two bits are always fixed to 0.

Bit	Bit Name	Initial Value	R/W	Description
31 to 2 1, 0	CAYR[31:2] CAYR[1:0]	H'0000 0000	R/W R	<ul style="list-style-type: none"> <li>• Frame image capture: These bits set the address for storing the Y (luminance) component data of the captured data (4-pixel units).</li> <li>• One-field image capture: These bits set the address for storing the Y (luminance) component data of the captured data (4-pixel units).</li> <li>• Both-field image capture: These bits set the address for storing the Y (luminance) component data of the captured top-field data (4-pixel units).</li> <li>• Data fetch: These bits set the address for storing data (4-byte units).</li> <li>• Data enable fetch bundle write: These bits set the address for storing data (32-byte units).</li> </ul>

Set the address of the starting point of the memory area where the fetched data is to be stored in this register, as shown in Figure 46.34.

- Frame image capture: Set the address of the starting point of the memory area where the Y component of the captured image is to be stored.
- One-field image capture: Set the address of the starting point of the memory area where the Y component of the captured image is to be stored.
- Both-field image capture: Set the address of the starting point of the memory area where the Y component of the captured top-field image is to be stored.
- Data fetch: Set the address of the starting point of the memory area where the fetched data is to be stored. In data fetch mode, the data is simply stuffed in order from the start address so the end address becomes as follows:

**End address = CDAYR + number of fetched bytes**

- Data enable fetch bundle write: Set the address in 32-byte units.

### 46.4.14 Capture Data Address C Register (CDACR)

CDACR specifies the address where the chrominance (C) component of the captured data is to be stored in frame image capture or one-field image capture, and the address where the chrominance (C) component of the captured top field is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. In frame image capture or one-field image capture, set the start address of the memory area where the C (chrominance) component of the captured data is to be stored by CDACR. In both-field image capture, set the start address of the memory area where the C (chrominance) component of the captured top-field image is to be stored by CDACR. CDACR is not used in data fetch.

Because the address must be specified in 32 bits, the address set by CDACR must be in longword units. As the setting is in 4-pixel units, the lower two bits are always fixed to 0.

Set the address of the starting point of the memory area where the C component of the captured image is to be stored in this register, as shown in Figure 46.35. The C component has an output data format like that in Figure 46.36, and is

saved in the memory in this format.

### 46.4.15 Capture Data Bottom-Field Address Y Register (CDBYR)

CDBYR specifies the address where the luminance (Y) component of the captured bottom-field data is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. Set the start address of the memory area where the Y (luminance) component of the captured bottom-field image is to be stored by CDBYR. CDBYR is not used in frame image capture, one-field image capture, or data fetch.

Because the address must be specified in 32 bits, the address set by CDBYR must be in longword units. As the setting is in 4-pixel units, the lower two bits are always fixed to 0.

Bit	Bit Name	Initial Value	R/W	Description

### 46.4.16 Capture Data Bottom-Field Address C Register (CDBCR)

CDBCR specifies the address where the chrominance (C) component of the captured bottom-field data is to be stored in both-field image capture. The CEU separates the captured image data into the luminance component data (Y) and the chrominance component data (C), and stores them in the memory via the bus. Set the start address of the memory area where the C (chrominance) component of the captured bottom-field image is to be stored by CDBCR. CDBCR is not used in frame image capture, one-field image capture, or data fetch.

Because the address must be specified in 32 bits, the address set by CDBCR must be in longword units. As the setting is in 4-pixel units, the lower two bits are always fixed to 0.

Bit	Bit Name	Initial Value	R/W	Description

### 46.4.17 Capture Bundle Destination Size Register (CBDSR)

CBDSR sets the size of output to memory in a bundle write. The number of output lines should be specified for image capture or data synchronous fetch. The number of bytes should be specified for data enable fetch.

22 to 0	CBVS[22:3] CBVS[2:0]	H'000	R/W R	These bits select the number of lines or number of bytes for output to the memory in a bundle write. Image capture and data synchronous fetch: Number of lines for output to the memory in a bundle write. #### (a) Image capture and data synchronous fetch

Set the number of lines of captured data to be written to the memory by a bundle write as a multiple of eight. This register is valid only when the CBE bit in CDOCR is 1. When the CBE bit in CDOCR is 1 and this register cleared to H'0, this module operates with the number of lines of captured data to be written to the memory as eight. The maximum number of lines that can be set is 768 (H'300). Only bits CBVS[11:3] are valid.

#### (b) Data enable fetch

Set the number of bytes of captured data to be written to the memory by a bundle write as a multiple of 32. This register is valid only when the CBE bit in CDOCR is 1. The minimum settable size is 512 bytes. When a number smaller than 512 bytes is specified, operation is not guaranteed.

### 46.4.18 Capture Low-Pass Filter Control Register (CLFCR)

CLFCR specifies whether or not to operate the low-pass filter. In data fetch mode, clear the LPF bit to B'0.

The characteristic of the low-pass filter installed in the CEU causes the phase location of the image processed by the low-pass filter to be shifted right by one pixel compared to the raw image.

### 46.4.19 Firewall Operation Control Register (CFWCR)

CFWCR specifies the upper limit of the write addresses in data enable fetch. When the VD input from an external module does not go low and end notification is not given, this register can prevent writing to memory from being out of control.

This register is enabled only in data enable fetch.

For data output from the CEU, the COLS, COWS, and COBS bits control swapping in 32-bit, 16-bit, and 8-bit units, respectively. Set these bits when data is misaligned because of a difference in endian. The data swapping bits are shown below. These bits can be set similarly in data fetch mode.

Data can be swapped in 8-bit, 16-bit, 32-bit units, or in 32 bits, 16 bits and 8 bits, as shown in Figure 46.44. To enable data swapping, set the corresponding control bit to B'1.

#### 46.4.22 Capture Event Flag Clear Register (CETCR)

CETCR notifies the CPU of the source of an interrupt that is generated in the CEU. The flags of CETCR can be used as interrupt signals. When the corresponding interrupt is enabled, an interrupt is generated. To clear the interrupt, clear the bit corresponding to the interrupt source to 0. After several cycles have passed after modifying the bit, the interrupt is cleared.

To clear the bit corresponding to the interrupt source to be cleared to 0 and retain that state, write 1 to that bit. For example, to clear only the CPE bit to 0, write H'FFFF FFFE to CETCR.

In CETCR, only bits to which 0 is written are cleared. Bits to which 1 is written retain their current values. To clear an interrupt source, write 0 only to the bit corresponding to the interrupt source to be cleared, and 1 to the other bits.

Note: Since the CETCR value becomes undefined in the following cases, clear all bits in CETCR to 0.

- VD and HD bits immediately after power-on reset or the deep-standby mode is entered
- All bits after the software standby or module standby mode is entered
- VD and HD bits after the polarities of the capture interface sync signals are changed

CSTSR indicates the internal status of the CEU. CSTSR differs from CETCR in that no interrupt is generated for the events indicated in CSTSR.

The CEU operating/halt state can be confirmed using CSTSR. To confirm the halt state of the CEU, make sure that the status bit (bit 0) indicating that the CEU is operating is cleared to 0 for sure.

In frame image capture or one-field image capture, set the start address of the memory area where the Y component of the captured data is to be stored by CDAYR2. In both-field image capture, set the start address of the memory area where the Y component of the captured top-field image is to be stored by CDAYR2. ## 46.5.3 Cooperation with Video Display Controller 5

Since the input data are written to the memory separately as Y data and CbCr data in image capture mode, the captured data cannot be displayed in the video display controller 5.

## 47. Pixel Format Converter

The pixel format converter has a color matrix that is used to adjust offsets and nine-axis gain for image data in the YCbCr or RGB format. This enables brightness adjustment, gain adjustment, and YCbCr and RGB mutual conversion. This LSI incorporates two channels of pixel format converters.

#### 47.2.4 PFV Input Buffer Register (PFVID)

PFVID is 32-byte buffer memory that stores pixel data to be converted. The buffer memory has a FIFO structure (FIFO buffer). If an attempt is made to write data to the input buffer while it does not have empty space, the input FIFO overflow interrupt flag is set to 1; the written data is ignored in this case.

#### 47.2.5 PFV Output Buffer Register (PFVOD)

PFVOD is 32-byte buffer memory that stores the converted pixel data. The buffer memory has a FIFO structure (FIFO buffer). If an attempt is made to read data from the output buffer while it does not have valid data, the output FIFO underflow interrupt flag is set to 1; the read data is undefined in this case.

### 47.3.4 Bit Reduction

For RGB565 output, the number of RGB data bits is reduced from eight bits to six or five bits. The operation mode can be selected from round-off mode and  $2 \times 2$  pattern dither mode through the DTH\_ON bit in PFVCR. When selecting  $2 \times 2$  pattern dither mode, be sure to set up the PFVSZX and PFVSZY bits in PFVSZR.

From the values set in the PFVSZX and PFVSZY bits in PFVSZR, this module generates horizontal and vertical sync signals.

The following shows the specifications of  $2 \times 2$  pattern dither operation.

**Figure 47.2 Specifications of  $2 \times 2$  Pattern Dither Operation**

The conversion equations are as follows.

- Round-off mode

1. 8 bits to 6 bits

$$\text{Output RGB data}[7:2] = \text{Input RGB data}[7:0] \div 4 \text{ (round off to an integer)}$$

2. 8 bits to 5 bits

$$\text{Output RGB data}[7:3] = \text{Input RGB data}[7:0] \div 8 \text{ (round off to an integer)}$$

- $2 \times 2$  pattern dither

1. 8 bits to 6 bits

$$\text{Output RGB data}[7:2] = \text{Input RGB data}[7:0] \div 4 + \text{pattern value at the first decimal place (truncate the number below the decimal point after addition)}$$

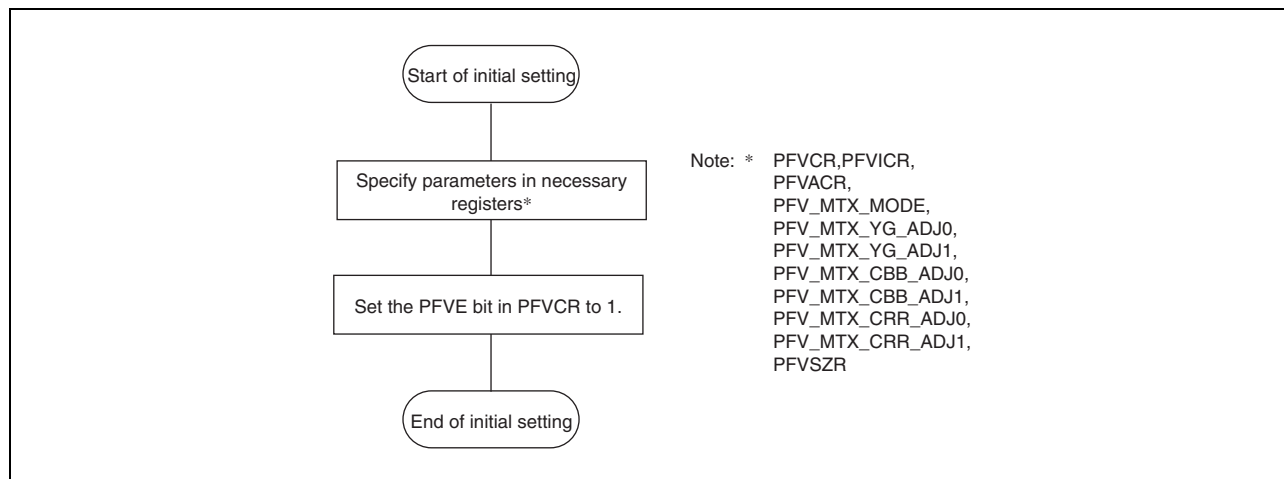

2. 8 bits to 5 bits

$$\text{Output RGB data}[7:3] = \text{Input RGB data}[7:0] \div 32 + \text{pattern value at the first decimal place (truncate the number below the decimal point after addition)}$$

## 47.4 Interrupt Requests

This module has three interrupt requests: input FIFO empty, output FIFO full, and PFV error. Table 47.4 summarizes the interrupt requests.

**Table 47.4 List of Interrupt Requests**

Interrupt Request	Abbreviation	Interrupt Request Condition	DMAC Activation
Input FIFO empty	IFEI	(PFVISR.IFEMP = 1) & (PFVICR.IFEN = 1)	Possible
Output FIFO full	OFFI	(PFVISR.OFFUL = 1) & (PFVICR.OFEN = 1)	Possible
PFV error	PFVEI	((PFVISR.IFOVF=1)   (PFVISR.OFUDF=1)) & (PFVICR.PFVEEN=1)	Not possible

When an interrupt condition shown in Table 47.4 becomes 1, this module sends an interrupt request. The input FIFO empty and output FIFO full interrupt requests can activate the direct memory access controller when the direct memory access controller is set to allow this. In this case, the interrupts from this module are not sent to the CPU.

## 48. SCUX

The SCUX consists of sampling converters, digital volume units, and a mixer. It is connected to the SSIF module to have an interface with external modules.

### 48.1 Features

Note 1. The synchronous mode can be selected only when the SCUX is connected to the FFD and FFU modules. For details, refer to section 48.4.5.

Note 2. The selectable sampling rates depend on the number of used channels and rate ratio. For details, refer to section 48.3.22 and section 48.4.7.

Note 3. The data format is a 24-bit value.

Note 4. The number of selectable channels depends on the sampling rate and route. For details, refer to section 48.4.7.

#### (2) [DVU] Digital Volume and Mute Functions

- Digital volume, volume ramp, and zero cross mute are provided as functions to adjust the volume
- The digital volume is set as a 24-bit fixed-point value within the range from a multiple of 0 to 8 (mute, -120 to 18 dB)
- Volume ramp can be used to perform soft mute, fade in, fade out, and volume change as desired
- The ramp time of volume ramp can be changed and set within the sampling range of  $2^0$  to  $2^{23}$
- Zero cross mute turns the sound mute at the zero cross point of audio data
- Direct transfer with the SSIF module and transfer with the mixer are possible

#### (3) [MIX] Mixer

- Data of two to four source systems can be mixed (added together) into one system
- The ratio to add the sources can be set
- The ratio can be changed dynamically
- Volume ramp enables mixing to be performed (ramp time is variable)

### 48.3.22 2SRC0\_m IFS Value Setting Register p (IFSVRp\_2SRC0\_m) (m = 0, 1; p = 0, 1)

IFSVRp\_2SRC0\_m is a 32-bit readable/writable register that sets the INTIFS value.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	INTIFS											
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	INTIFS															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27 to 0	INTIFS	All 0	R/W	Initial Value of FSI These bits set initial value of FSI. Set the input sampling rate and output sampling rate within the restricted range determined by the number of channels. Example: Fin = 32 kHz Fout = 44.1 kHz FSI = $2^{22} * 32000/44100 = 3043485 = 0x02E709D$

When using the SRC in asynchronous mode, INTIFS is given as the initial value of FSI, which is the sampling conversion function. Therefore, after setting the INTIFSEN bit in IFSCRp\_2SRC0\_m to 1, set the INTIFS bits to the desired value. The SRC automatically detects the input sampling frequency and output sampling frequency. Based on this, the FSI value is calculated so that the following equation is satisfied.

$$\frac{F_{in}}{F_{out}} \approx \frac{FSI}{FSO}$$

[Legend]

Fin: Input sampling frequency

Fout: Output sampling frequency

FSI: Input sampling rate

FSO: Output sampling rate (fixed value:  $2^{22} = 0x0400000$ )

When using the SRC in synchronous mode, the value set in INTIFS is used as the FSI value from beginning to end. The value set in INITFS is shown in Table 48.3 to Table 48.8.

### 48.3.65 DMA Transfer Register for FFD0\_n (DMATDn\_CIM) (n = 0, 1, 2, 3)

DMATDn\_CIM is a 32-bit register that stores the data to be transmitted to FFD0\_n. The data written to DMATDn\_CIM is automatically stored in FFD0\_n. When the number of data bytes in FFD0\_n becomes equal to or smaller than the value set in DRQSR\_FFD0\_0.SIZE, a data transfer request is issued. When the DMA controller is used (DMACR\_CIM.DMAMDFFDn = 1), a transfer request for the number of counts set in DRQSR\_FFD0\_0.SIZE is sent to the DMA controller. When the interrupt controller is used (DEVMR\_FFD0\_n.DEVMRQ = 1), data is written in this register for the number of counts set in DRQSR\_FFD0\_0.SIZE.

In the SCUX internal block, audio data is handled in the 24-bit big endian format. When this register is accessed in 32-bit units, the lower eight bits are not used and only the upper 24 bits are used, as shown in Figure 48.2. When the SCUX is used in 16-bit mode, the valid data needs to be located at the MSB of audio data. Therefore, when this register is accessed in 16-bit units, the written data is located in the upper 16 bits of audio data and the lower eight bits are fixed to 0 in the CIM block. When the SCUX is used in 16-bit mode and this register is accessed in 32-bit units, since bits [15:8] of the data to be written is passed to the FFD block without change, 0 should be written to bits [15:8].

### 48.3.66 DMA Transfer Register for FFU0\_n (DMATUn\_CIM) (n = 0, 1, 2, 3)

DMATUn\_CIM is a 32-bit register that stores the data received from FFU0\_n. When data is read from DMATUn\_CIM, the next data is automatically transferred from FFU0\_n. When the number of data bytes in FFU0\_n becomes equal to or greater than the value set in URQSR\_FFU0\_n.SIZE, a data transfer request is issued. When the DMA controller is used (DMACR\_CIM.DMAMDFFU<sub>n</sub> = 1), a transfer request for the number of counts set in URQSR\_FFU0\_n.SIZE is sent to the DMA controller. When the interrupt controller is used (UEVMR\_FFU0\_n.UEVMRQ = 1), data is read from this register for the number of counts set in DRQSR\_FFD0\_0.SIZE.

When this register is accessed in 32-bit units, audio data is located in the upper 24 bits and the lower eight bits are always read as 0, as shown in Figure 48.3. When this register is accessed in 16-bit units, the upper 16 bits of audio data are read as valid data. When the SCUX is used in 16-bit mode and this register is accessed in 32-bit units, the lower eight bits are always read as 0 and bits [15:8] of the read data are read as a value dependent on the internal operation result in the SRC.

Note: \* All 1 when the internal operation result of the SRC is 0x7FFFFFFF; otherwise, all 0.  
 Even when used in 16-bit mode, operation is performed in 24-bit units.

### 48.3.67 SSI Route Select Register (SSIRSEL\_CIM)

SSIRSEL\_CIM is a 32-bit readable/writable register that selects the SSIF channel to be connected to each SRC during direct transfer with the SSIF module. This register setting has no meaning when a route between the FFD or FFU module is selected. The IPLSR\_IPC0\_n and OPSLR\_OPC0\_n registers are used to select connection between the SSIF or FFD/FFU module. The DVUBR\_DVU0\_n register is used to specify whether the DVU is used or not.

### 48.4.3 Data Rearrangement for Each Channel

Data can be rearranged independently for each channel in the SCUX. Data rearrangement can be performed immediately before input to the SRC and immediately after output from the MIX. Table 48.9 to Table 48.11 show definition of data places. Data rearrangement immediately before the SRC is performed as described in section 48.3.72, SRCn Route Select Register (SRCRSELn\_CIM) (n = 0, 1, 2, 3). Data rearrangement immediately after the MIX is performed as described in section 48.3.73, MIX Route Select Register (MIXRSEL\_CIM).

### 48.4.4 Pin Connection Specifications of SSIF

SSIF0 to SSIF3 and SSIF3 to SSIF5 can be operated in synchronization with the same SSISCK and SSIWS signals. The AUDIO\_CLK input to the SSIF can be selected between external pins AUDIO\_CLK and MLB\_CLK. These settings are made as described in section 48.3.70, SSI Pin Mode Register (SSIPMD\_CIM). Figure 48.12 shows the pin connection specifications of each SSIF module.

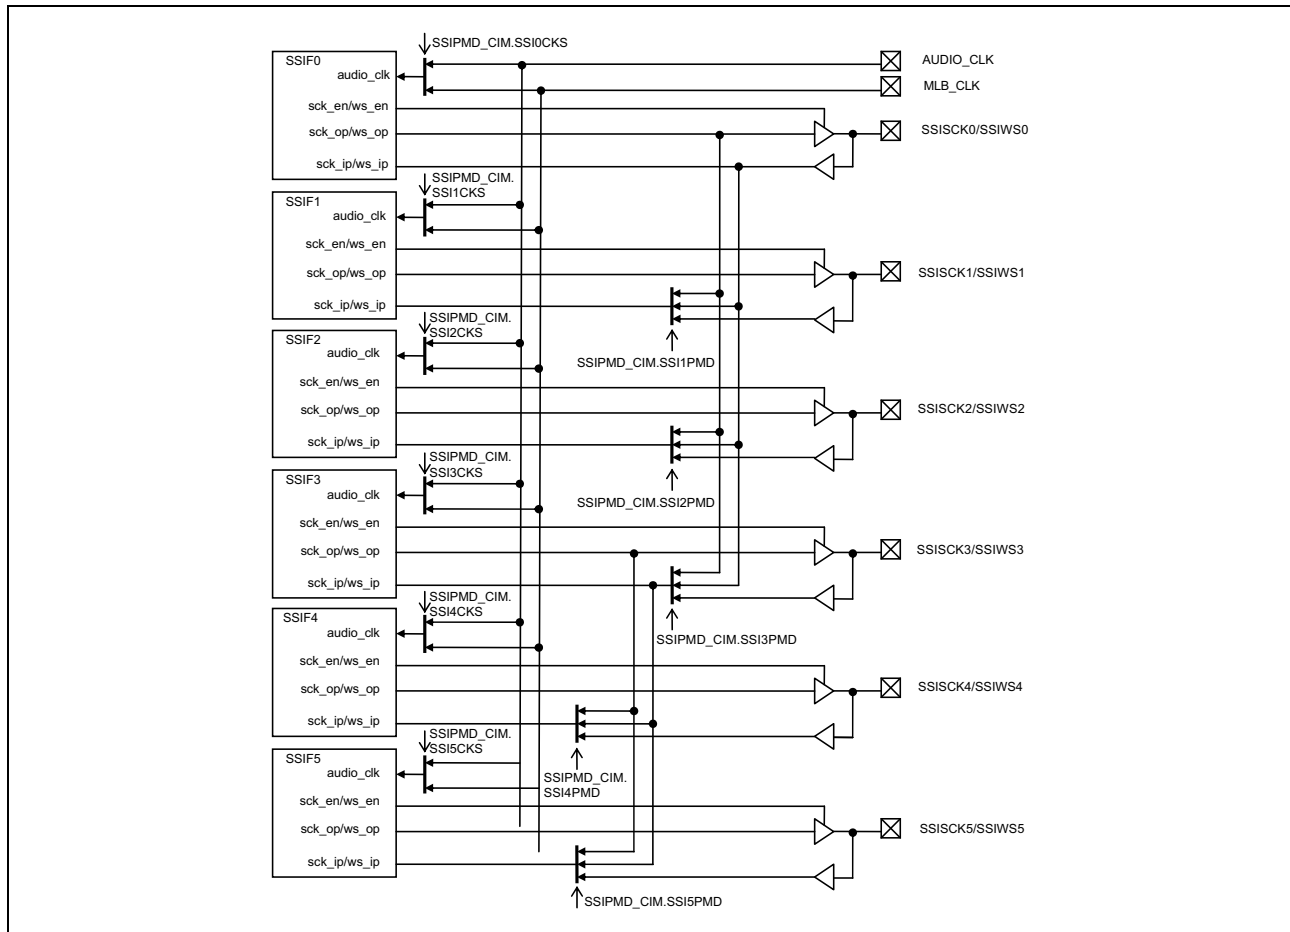

Figure 48.12 Pin Connection Specifications of SSIF

### 48.4.5 Data Transfer Route

Table 48.12 to Table 48.14 list the data transfer routes that can be selected by the SCUX.

Table 48.15 to Table 48.17 show the necessary register settings for selecting each transfer route.

The 2SRC0\_m bypass register p and DVU0\_n bypass register should be set appropriately to bypass the SRC and DVU, respectively.

### 48.4.6 Input Timing Signal and Output Timing Signal

The input timing signal and output timing signal need to be set when using the SRC or MIX. Table 48.18 to Table 48.20 show the input/output timing setting necessary for each transfer route in Table 48.12 to Table 48.14. When direct connection between the SRC and SSIF is selected, the WS signal of the relevant SSIF is automatically selected regardless of the setting of the FFD0\_n/FFU0\_n timing select register. When direct connection between the MIX and SSIF is selected, set the prescribed value in the FFU0\_n timing select register. When connection between the FFD and SRC or connection between the SRC and FFU is selected, a desired value can be set in the FFD0\_n/FFU0\_n timing select register and timing signals corresponding to the setting are used.

### 48.4.7 2SRC (SRC) Block

The 2SRC block consists of two SRCs (Sampling Rate Converters) which implement the sampling rate conversion function. Each SRC has two modes allowing either synchronous or asynchronous sampling rate conversion to be performed.

- Asynchronous or synchronous sampling rate conversion is possible\*<sup>1</sup>
- Sampling rate (synchronous mode)\*<sup>2</sup>  
Input [KHz]: 8, 11.025, 12, 16, 22.05, 24, 32, 44.1, 48, 64, 88.2, or 96 is selectable  
Output [KHz]: 8, 16, 24, 32, 44.1, 48, or 96 is selectable
- Sampling rate (asynchronous mode)\*<sup>2</sup>  
Input/output [KHz]: 1 to 96
- The supported number of bits is 16 bits and 24 bits
- Sound quality: -132 dB or less\*<sup>3</sup>
- Supports 1, 2, 4, 6, or 8 channels\*<sup>4</sup>
- DMA transfer with on-chip memory or external memory and direct transfer with the SSIF module are possible

Note 1. The synchronous mode can be selected only when the SCUX is connected to the FFD and FFU modules.

Note 2. The selectable sampling rates depend on the number of used channels and rate ratio.

Note 3. The data format is a 24-bit value.

Note 4. The number of selectable channels depends on the sampling rate and route.

Figure 48.13 shows a block diagram of the 2SRC (SRC) block. Input audio data indicates the data before executing the SRC function and output audio data indicates the data after executing the SRC function.

In synchronous SRC mode, the 2SRC (SRC) block outputs the input request signal to the FFD block and outputs the output request signal to the FFU block. In asynchronous SRC mode, the 2SRC (SRC) block receives the input timing signal and output timing signal from an external module and automatically detects the input sampling rate and output sampling rate from these timing signals.

Each SRC in the 2SRC (SRC) block can simultaneously process audio data for a maximum of eight channels. However, the maximum sampling rate that can be handled depends on the number of channels used. When SRC2 or SRC3 is used by the route from the FFD or the route to the FFU, the maximum number of processable channels is two. The number of channels is set by `SADIRp_2SRC0_m.CHNUM`. When not in bypass mode (`SRCBRp_2SRC0_m.BYPASS = 0`), unused channels always output 0 after initialization (`SRCIRp_2SRC0_m.INIT = 1`) unless the `CHNUM` setting is changed. In bypass mode, the input audio data is output one cycle later in all channels regardless of the `CHNUM` setting.

The bit width of output audio data can be set to 16 bits or 24 bits by `SADIRp_2SRC0_m.OTBL`. For input audio data, audio data with the same bit width as the `OTBL` bit setting in Table 48.21 should be input.

#### 48.4.8 DVU Block

The DVU block is used to control volume and mute. This block can simultaneously process data for a maximum of eight channels.

- Digital volume, volume ramp, and zero cross mute are provided as functions to adjust the volume
- The digital volume is set as a 24-bit fixed-point value within the range from a multiple of 0 to 8 (mute, -120 to 18 dB)
- Volume ramp can be used to perform soft mute, fade in, fade out, and volume change as desired
- The ramp time of volume ramp can be changed and set within the sampling range of  $2^0$  to  $2^{23}$
- Zero cross mute turns the sound mute at the zero cross point of audio data
- Direct transfer with the SSIF module and transfer with the mixer are possible

The number of channels is set by VADIR\_DVU0\_n.CHNUM. For unused channels, the input data that is input to the corresponding channels is output one cycle later. In bypass mode, the input data is output one cycle later in all channels regardless of the CHNUM setting.

### Operation

- (1) In the initialized state ( $DVUIR\_DVU0\_n.INIT = 1$ ), set the  $VVMD$  bit in  $DVUCR\_DVU0\_n$  to 1 (digital volume mode) and the  $VOLVALm$  bit in  $VOL0R\_DVU0\_n$  to  $24'H10\_0000$  (0 dB). Until the initialized state is cleared, the DVU does not start operation and its output data is 0.
- (2) When the initialized state is cleared ( $DVUIR\_DVU0\_n.INIT = 0$ ), the DVU starts operation. Since the  $VOLVALm$  bit is set to 0 dB, the output data is the same size as the input data.
- (3) Set the  $DVUEN$  bit in  $DVUER\_DVU0\_n$  to 0 and the  $VOLVAL0$  bit in  $VOL0R\_DVU0\_n$  to  $24'H05\_0F45$  (-10 dB).
- (4) The setting to the  $VOLVAL0$  bit in (3) is enabled by setting the  $DVUEN$  bit in  $DVUER\_DVU0\_n$  to 1. The output data is the value obtained by attenuating the input data by -10 dB.

Figure 48.16 shows the image of volume ramp operation.

Figure 48.16 Volume Ramp Operation

### Operation

- (1) In the initialized state ( $DVUIR\_DVU0\_n.INIT = 1$ ), set the VRMD bit in  $DVUCR\_DVU0\_n$  to 1 (volume ramp mode) and the VRENm (m: arbitrary value from 0 to 7) bit in  $VRCTR\_DVU0\_n$  to 1. Until the initialized state is cleared, the DVU does not start operation and its output data is 0.
  - (2) When the initialized state is cleared ( $DVUIR\_DVU0\_n.INIT = 0$ ), the DVU starts operation.
- Note: Changes to the settings of the VRDB bit of the  $VRDBR\_DVU0\_n$  register made in the INIT state rapidly become applicable on release from the INIT state (independently of the setting of  $VRWTR\_DVU0\_n$  and  $VRPDR\_DVU0\_n$ ).
- (3) Set the DVUEN bit in  $DVUER\_DVU0\_n$  to 0, the VRPDDW bit in  $VRPDR\_DVU0\_n$  to 5'H0F (0.125 dB/32 steps), the VRDB bit in  $VRDBR\_DVU0\_n$  to 10'H064 (-12.5 dB), and the VRWT bit in  $VRWTR\_DVU0\_n$  to 24'H00\_113A (4410 samples).
  - (4) The setting in (3) is enabled by setting the DVUEN bit in  $DVUER\_DVU0\_n$  to 1.
  - (5) The VDU waits to start the volume ramp operation for  $4410/44100 = 0.1$  second because the sampling rate is set to 44.1 kHz with  $VRWTR\_DVU0\_n.VRWT = 24'H00_113A$  (4410 samples).
  - (6) The VDU starts volume ramp operation after the wait time in (5).  
The output data is the value obtained by attenuating the input data by -12.5 dB after  $12.5 \times 32/0.125 = 3200$  steps because the VRPDDW bit in  $VRPDR\_DVU0\_n$  is set to 5'H0F (0.125 dB/32 steps) according to 0 dB to -12.5 dB ramp down.
  - (7) Set the DVUEN bit in  $DVUER\_DVU0\_n$  to 0, the VRPDUP bit in  $VRPDR\_DVU0\_n$  to 5'H0C (0.125 dB/4 steps), the VRDB bit in  $VRDBR\_DVU0\_n$  to 10'H000 (0 dB), and the VRWT bit in  $VRWTR\_DVU0\_n$  to 24'H00\_0000 (0 sample).
  - (8) The setting in (7) is enabled by setting the DVUEN bit in  $DVUER\_DVU0\_n$  to 1.
  - (9) The VDU starts volume ramp operation without delay because the VRWT bit in  $VRWTR\_DVU0\_n$  is set to 24'H00\_0000 (0 sample).  
The output data is the same size as the input data after  $12.5 \times 4/0.125 = 400$  steps because the VRPDUP bit in  $VRPDR\_DVU0\_n$  is set to 5'H0C (0.125 dB/4 steps) according to -12.5 dB to 0 dB ramp up.

### 48.4.9 MIX Block

The MIX block is used to mix (add together) the input audio data from a maximum of four systems into one system. Each system can simultaneously process data for a maximum of eight channels.

- Data of two to four source systems can be mixed (added together) into one system
- The ratio to add the sources can be set
- The ratio can be changed dynamically
- Volume ramp enables mixing to be performed (ramp time is variable)
- Only direct transfer with the SSIF module is possible

The number of channels is set by `MADIR_MIX0_0.CHNUM`. When not in bypass mode (`MIXBR_MIX0_0.BYPASS = 0`), unused channels always output 0 after initialization (`MIXIR_MIX0_0.INIT = 1`) unless the `CHNUM` setting is changed. In bypass mode, the input data is output one cycle later in all channels regardless of the `CHNUM` setting. Figure 48.17 shows a block diagram of the MIX block.

**Figure 48.17 Block Diagram of MIX Block**

Table 48.26 shows the functions of the MIX block.

**Table 48.26 MIX Block Functions**

Item	Performance
Volume step mixer	Mix the data of four systems into one system. The volume of each system can be adjusted by step change.
Volume ramp mixer	Mix the data of four systems into one system. The volume of each system can be adjusted by ramp.

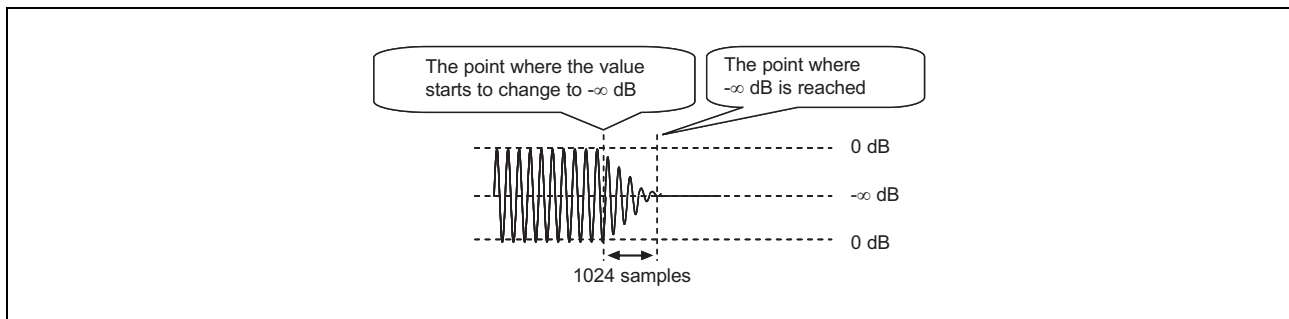

Figure 48.18 shows the image of volume step operation for 1-system data. This figure explains about the operation when the volume is changed from 0 dB to  $-\infty$  dB. The volume can change the target dB for one step each. In the case of the volume step mixer, the volume of four systems can be adjusted at each step change (one sample).

Figure 48.19 shows the image of volume ramp operation for 1-system data. This figure explains about the operation when the volume is changed from 0 dB to  $-\infty$  dB. The volume can be changed by 0.125-dB/step each and it takes 1024 samples to reach  $-\infty$  dB in the maximum case for each system. In the case of the volume ramp mixer, the volume of four

systems can be adjusted at each ramp. In addition, the volume ramp mixer has a mechanism to reduce the noise. If the direction of volume is different among the four systems, it operates from the volume-down systems and after that operates on the volume-up systems automatically. In the case of the same direction, it changes the volume at the same timing.

### Operation

- (1) In the initialized state (MIXIR\_MIX0\_0.INIT = 1), set the MIXMODE bit in MIXMR\_MIX0\_0 to 1 (volume ramp mode) and the MXPDDW bit in MVPDR\_MIX0\_0 to 4'HA (0.125 dB/1 sample).

Until the initialized state is cleared, the MIX does not start operation and its output data is 0.

- (2) When the initialized state is cleared (MIXIR\_MIX0\_0.INIT = 0), the MIX starts operation.

**Note:** Changes to the settings of the MIXDBA bits of the MDBAR\_MIX0\_0 register, MIXDBB bits of the MDBBR\_MIX0\_0 register, MIXDBC bits of the MDBCR\_MIX0\_0 register and MIXDBD bits of the MDBDR\_MIX0\_0 register made in the INIT state rapidly become applicable on release from the INIT state (independently of the setting of MVPDR\_MIX0\_0).

- (3) Set as follows:

MDBER\_MIX0\_0.MIXDBEN = 0

MDBAR\_MIX0\_0.MIXDBA = 10'H0C8 (-25 dB)

MDBBR\_MIX0\_0.MIXDBB = 10'H0C8 (-25 dB)

MDBCR\_MIX0\_0.MIXDBC = 10'H0C8 (-25 dB)

MDBDR\_MIX0\_0.MIXDBD = 10'H0C8 (-25 dB)

- (4) The setting in (3) is enabled by setting the MIXDBEN bit in MDBER\_MIX0\_0 to 1.

- (5) The output data is the value obtained by attenuating and mixing the input data of each system by -25 dB after  $25/0.125 = 200$  steps because the MXPDDW bit in MVPDR\_MIX0\_0 is set to 4'HA (0.125 dB/1 sample) according to 0 dB to -25 dB ramp down for each system.

- (6) Set as follows:

MDBER\_MIX0\_0.MIXDBEN = 0

MDBAR\_MIX0\_0.MIXDBA = 10'H000 (0 dB)

MDBBR\_MIX0\_0.MIXDBB = 10'H000 (0 dB)

MDBCR\_MIX0\_0.MIXDBC = 10'H000 (0 dB)

MDBDR\_MIX0\_0.MIXDBD = 10'H000 (0 dB)

- (7) The setting in (6) is enabled by setting the MIXDBEN bit in MDBER\_MIX0\_0 to 1.

- (8) The output data is the value obtained by boosting and mixing the input data of each system by 25 dB after  $25/0.125 = 200$  steps because the MXPDU bit in MVPDR\_MIX0\_0 is set to 4'HA (0.125 dB/1 sample) according to -25 dB to 0 dB ramp up for each system.

## 49.4 Operation

### 49.4.1 Base Operation

#### (1) Initial Settings

Make sure that this module has stopped before setting registers.

The operation stop procedure, operating clock, and attenuator function on/off settings are specified by the STPM, SGCK, and DPF bits in SGCR1, respectively. When the attenuator function is on, the attenuation cycle is selected. The interrupt request is set by the SGIE bit in SGCSR.

#### (2) Activation

The operation of this module is enabled by setting the SGST bit in SGCR1 to 1 and clearing the SGEND bit in SGCR2 to 0. Set the TCHG bit in SGCR2 to 1 to cancel the write protect for SGSFR and SGTFR. Use bits SFS7 to SFS0 in SGSFR to select the reference frequency and bits TONE6 to TONE0 in SGTFR to select the tone frequency. SGLR specifies the output pulse duty. This module starts operation after writing to SGCR2, SGLR, SGTFR, and SGSFR is completed.

#### (3) Stopping

The operation stop procedure of this module is specified by the STPM bit in SGCR1.

When the attenuator function is off and STPM is 0, the operation is stopped by the SGST bit regardless of the SGEND bit setting. When the attenuator function is off and STPM is 1, the operation is stopped by clearing the SGST bit to 0 and setting the SGEND bit to 1.

When the attenuator function is on and STPM is 0, clearing the SGST bit to 0 stops operation even though the automatic attenuation does not end and the SGDEF bit is not set to 1. When the attenuator function is on and STPM is 1, clearing the SGST bit to 0 does not stop operation until the automatic attenuation ends and the SGDEF bit is set to 1.

The conditions for stopping this module are listed in Table 49.3 and examples of stopping operation are shown in Figure 49.2.

**Table 49.3 Stop Conditions**

Attenuator Function Off					Attenuator Function On

### 49.4.2 Tone Frequency Setting

This module provides tone frequency output in the range of 25 Hz to 20 kHz, with precision of 1% or less. The tone frequency is calculated by:

$$\begin{aligned} \text{Reference frequency (Hz)} &= \text{SGCLK (Hz)}/\text{SFS} \\ \text{Tone frequency (Hz)} &= \text{Reference frequency (Hz)}/(2 \times \text{TONE}) \\ &= \text{SGCLK (Hz)}/(2 \times \text{SFS} \times \text{TONE}) \end{aligned}$$

Setting values of the TONE bits in SGTFR and SFS bits in SGFSR are calculated by:

$$\begin{aligned} \text{SFS} &= \text{SGCLK (Hz)}/\text{reference frequency (Hz)} \quad (0 < \text{SFS} \leq 255) \\ \text{TONE} &= \text{Reference frequency (Hz)}/(2 \times \text{TONE frequency (Hz)}) \quad (0 < \text{TONE} \leq 127) \end{aligned}$$

An example of relationship between the tone frequency and output error is shown in Table 49.4.

**Table 49.4 Relationship between Tone Frequency and Output Error**

Tone Frequency	SFS[7:0]	TONE[6:0]	Error (%)
220.00	B1	6B	0.008
329.63	9E	50	0.007
440.00	4D	7B	0.02
659.26	4F	50	0.007
880.00	40	4A	0.03
1318.50	28	4F	0.005
1760.00	20	4A	0.03
2637.00	14	4F	0.005
3520.00	10	4A	0.03
5274.00	A	4F	0.005
7040.00	8	4A	0.03

Note: • SGCLK = P0φ [MHz]/4 = 33.33 [MHz]/4 = 8.3 [MHz]

Since changing P0φ frequency affects the tone frequency, care should be taken when changing it.

### 49.4.3 Auto Attenuator Function

When the auto attenuator function is on, the loudness data (LD) determines the initial duty cycle for SGOUT. The SGOUT duty cycle is attenuated by a factor of 1/32 using the attenuation cycle set by the DPF bits in SGCR1. The attenuation characteristics are calculated by the equation:

$$LD_n = \text{int} (LD_0 \times (1 - 1/32)^n)$$

LD: SGOUT duty cycle (The initial data is SGLR.)

n: Attenuation cycle number

Figure 49.4 is a graph of attenuation characteristics.

Figure 49.4 Attenuation Characteristics

### 49.4.4 Output Waveform

As shown in Figure 49.5, the output waveform of this module is obtained by synthesis of the on-chip 8-bit PWM pulse output and the tone frequency output. The duty cycle for the on-chip 8-bit PWM pulse output is set by SGLR.

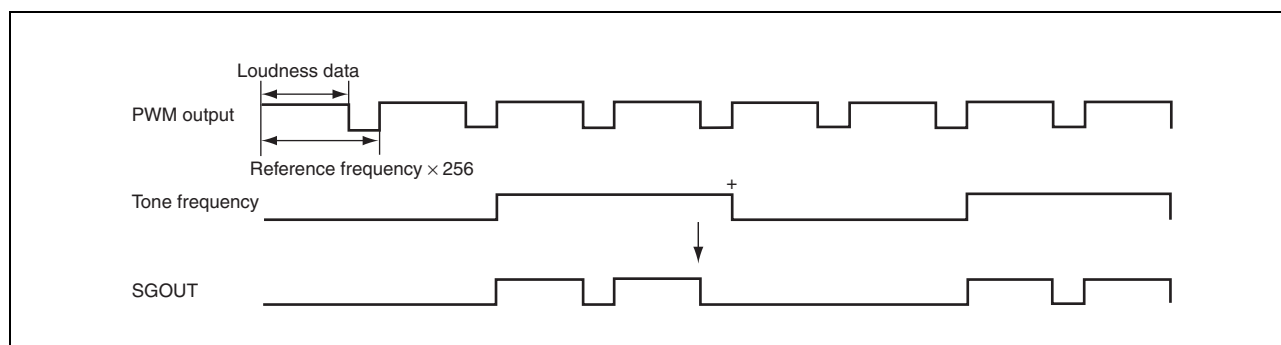

Figure 49.5 Output Waveforms

## 49.5 Interrupt Source

When the attenuator function is on and an automatic attenuation operation is completed (duty cycle for the on-chip PWM pulse output is 0), the SGDEF bit in SGCSR is set. An interrupt request is issued if the SGIE bit in SGCSR is set to 1. When STPM = 0, the SGDEF bit is set only when the first attenuation operation is completed. If the SGDEF bit is cleared during automatic attenuation, the SGDEF bit is set when the next attenuation operation is completed.

### 51.3.1 Command Setting Register (CE\_CMD\_SET)

CE\_CMD\_SET sets a command sequence.

The command sequence starts when the settings have been made in bits 31 to 16. Note that writing to CE\_CMD\_SET is disabled while a command sequence is proceeding (i.e., the value of CMDSEQ in CE\_HOST\_STS1 is 1).

CE\_CMD\_SET should be set according to the description in section 51.7.12, Setting Values of CE\_CMD\_SET. This register should be accessed in 16 bits. (The address of bits 31 to 16 is H'E804C800 and that of bits 15 to 0 is H'E804C802.)

### 51.3.11 Interrupt Flag Register (CE\_INT)

CE\_INT indicates various status during execution of a command sequence. Each bit is set to 1 when its setting condition has been met. To clear flag(s), write 0 only to the bit(s) to be cleared and write 1 to the other bits.

For the operation in the case of an error or timeout, see section 51.6.7, Operation in the Case of Error/Timeout.

## 51.4 Interrupt Requests

Table 51.3 shows the interrupt request specifications of this module.

This module generates three types of interrupt requests: normal operation, error/timeout, and card detection. When an interrupt flag is set to 1 and also the corresponding interrupt is enabled, an interrupt request is asserted.

## 51.5 DMA Specifications

This module provides two channels for DMA transfer requests: one for buffer reading and the other for buffer writing.

### 51.5.1 DMA for Buffer Writing

The DMA transfer request is asserted for buffer writing when the buffer has become empty while the DMAWEN bit in CE\_BUF\_ACC is 1.

The DMA transfer request stays asserted for the amount of data specified by BLKSIZ (the block size set in CE\_BLOCK\_SET)  $\times$  BLKCNT (the number of blocks for transfer set in CE\_BLOCK\_SET), and negated after the last block has been transferred. Note that the BUFWEN bit in CE\_INT will not be asserted in this case.

If an error occurs during DMA transfer or DMA transfer is forcibly terminated, the command sequence is stopped automatically, which causes the DMA transfer request to be negated.

### 51.5.2 DMA for Buffer Reading

The DMA transfer request is asserted for buffer reading when the buffer stores data of the block size specified in CE\_BLOCK\_SET while the DMAREN bit in CE\_BUF\_ACC is 1.

The DMA transfer request stays asserted for the amount of data specified by BLKSIZ (the block size set in CE\_BLOCK\_SET)  $\times$  BLKCNT (the number of blocks for transfer set in CE\_BLOCK\_SET), and negated after the last block has been transferred. Note that the BUFREN bit in CE\_INT will not be asserted in this case.

If an error occurs during DMA transfer or DMA transfer is forcibly terminated, the command sequence is stopped automatically, which causes the DMA transfer request to be negated.

## 51.6 Operation

### 51.6.1 Command/Response Formats

Figure 51.2 shows the format of the command to be transferred. The command index that is set in CMD[5:0] of CE\_CMD\_SET and the argument set in ARG[31:0] of CE\_ARG are reflected in the command.

**Figure 51.2 Command Format**

Figure 51.3 and Figure 51.4 show the formats when a 6-byte response and 17-byte response (R2) are received, respectively. The response index is stored in RSPIDX[5:0] of CE\_HOST\_STS1, and the status value of the response is stored to CE\_RESP0 or CE\_RESP3 to CE\_RESP0.

**Figure 51.3 Format of 6-Byte Response**

**Figure 51.4 Format of 17-Byte Response (R2)**

### 51.6.2 Data Block Format

Figure 51.5 shows the format of data blocks. For details on D0 to D3 in Figure 51.5, see section 51.6.3, Buffer Structure and Buffer Accesses. When data is written to a card, data stored in the buffer is transmitted. When data is read from a card, receive data is stored to the buffer.

Figure 51.5 Data Block Format

### 51.6.3 Buffer Structure and Buffer Accesses

This module has two units of 512-byte RAM as shown in Figure 51.6. Therefore, for multi-block writing, if one block of data (512 bytes) stored in one buffer has been transmitted but the other buffer is full, the next block of data can be continuously transmitted. For multi-block reading, if one block of receive data (512 bytes) has been stored in one buffer but the other buffer is empty, the next block of receive data can be continuously stored in the buffer.

If neither of the buffers is empty for multi-block reading, the MMC clock is stopped and reception is suspended. When one of the buffers becomes empty, the MMC clock supply is started to start reception.

The buffer is accessed with CE\_DATA. CE\_DATA should be accessed for  $4 \times (n + 1)$  bytes ( $n = 0, 1, 2, 3, \dots, 127$ ).

Figure 51.6 Double Buffer Structure

The buffer access select function allows byte-wise swapping of data when the buffer is accessed by writing to or reading from CE\_DATA. This function is enabled by the setting of CE\_BUFF\_ACC. Figure 51.7 shows the specification of byte-wise swapping.

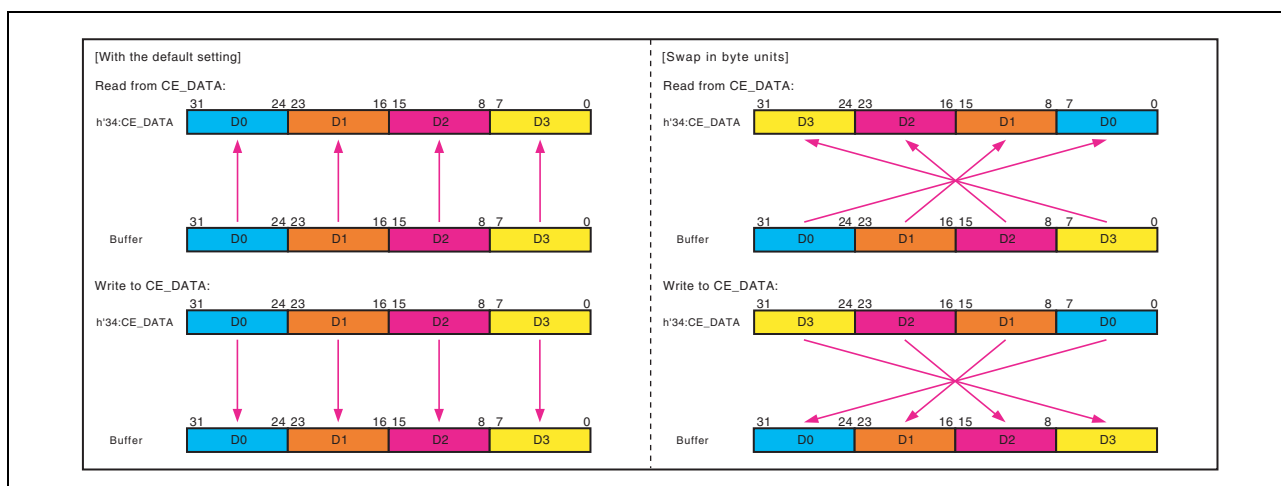

Figure 51.7 Specification of Byte-Wise Swapping

### 51.6.4 Automatic CMD12 Issuance

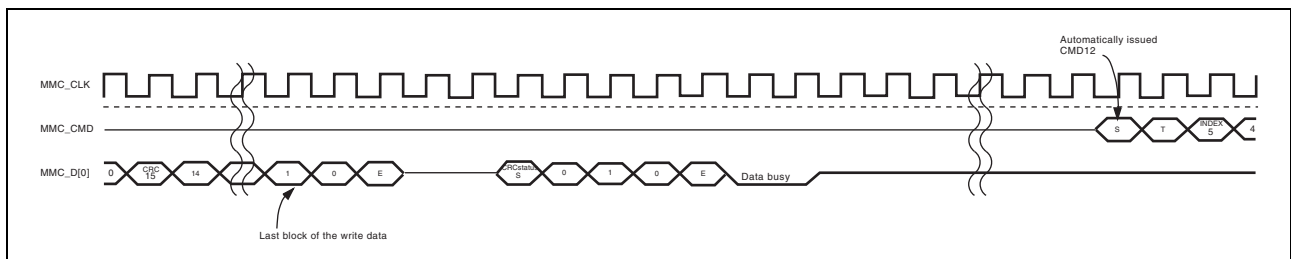

This module automatically issues CMD12 when multi-block transfer is performed with the CMD12EN bit in CE\_CMD\_SET set to 1.

Figure 51.8 shows the timing of automatic CMD12 issuance in multi-block read. CMD12 is issued such that the end bit of the command is sent two bits before the end bit of the data during reception of the last block.

**Figure 51.8** Timing of Automatically-Issued CMD12 in Multi-Block Read (1-Bit Mode)

Figure 51.9 shows the timing of automatic CMD12 issuance in multi-block write. CMD12 is issued after the data busy after transmission of the last block has ended.

**Figure 51.9** Timing of Automatically-Issued CMD12 in Multi-Block Write (1-Bit Mode)

The argument of the automatically-issued CMD12 is set by CE\_ARG\_CMD12. The value of [39:8] of the response to CMD12 is stored to CE\_RESP\_CMD12. The busy status on response reception is received.

### 51.6.5 High Priority Interrupt (HPI)

HPI should be executed as described below with reference to section 51.3, Register Descriptions and section 51.7, Examples of Setting.

#### (1) When HPI is executed during a write to the device

- (a) Terminate the command sequence forcibly.
- (b) Wait for the CMDSEQ bit in CE\_HOST\_STS1 to be cleared to 0.
- (c) Issue CMD12 (R1) to make the device in the rcv state enter the prg state. Note that the device does not output the response when the device is in the prg state before issuance of CMD12(R1).
- (d) Issue CMD13 (R1).
- (e) Issue the HPI command.

#### (2) When HPI is executed during response busy while not writing to the device

- (a) Terminate the command sequence forcibly.
- (b) Wait for the CMDSEQ bit in CE\_HOST\_STS1 to be cleared to 0.
- (c) Issue CMD13 (R1).
- (d) Issue the HPI command\*.

The procedure above is for HPI generated in the CMD6, CMD24, CMD25 (Pre-defined), or CMD38 sequence.

Note: \* CMD12 (R1b) or CMD13 (R1b) depending on the device connected

### 51.6.6 Background Operation

Background operation should be executed as described below with reference to section 51.3, Register Descriptions and section 51.7, Examples of Setting.

To execute background operation, issue CMD6 (R1) to write to the BKOPS\_START byte in the EXT\_CSD register of the device.

Completion of background operation can be determined by checking the device state with CMD13 (R1) issued after CMD6 (R1) or by polling MMCDAT[0]. When the device state is indicated as “tran” or MMCDAT[0] is high, background operation is determined to be completed.

To suspend background operation, use HPI described in section 51.6.5.

### 51.6.7 Operation in the Case of Error/Timeout

This module may not be stopped in case of error occurrence. If the command sequence is in progress when an error occurs (check the CMDSEQ bit in CE\_HOST\_STS1), terminate the sequence forcibly and perform a software reset. The data for transmission or received data that had been stored in the buffers at the time of error occurrence are not guaranteed.

This module is not stopped when a timeout has occurred. To execute the next command after a timeout error has occurred, terminate the sequence forcibly, perform a software reset.

For forcible termination, refer to section 51.7.11, Forcible Termination.

### 51.7 Examples of Setting

This section shows the procedures for executing typical command sequences.

## 51.8 Usage Note

### 51.8.1 Card Detection

The CDRISE and CDFALL bits in CE\_DETECT which are used for the card detection function do not have a chattering elimination function. The chattering elimination processing should be implemented by software.

### 51.8.2 Multi-Block Transfer

When HPI is executed, use pre-defined multi-block transfer.

## 52. Motor Control PWM Timer

This LSI has two channels of on-chip motor control PWM (pulse width modulator) timer with a maximum capability of eight pulse outputs for each channel.

### 52.1 Features

- Maximum of 16 pulse outputs
  - Two 10-bit PWM channels, each with eight outputs
  - 10-bit counter (PWCNT) and cycle register (PWCYR)
  - Duty and output polarity can be set for each output.
- Automatic data transfer in every cycle
  - Each of four duty registers (PWDTR) is provided with buffer registers (PWBFR), with data transferred automatically every cycle.
- Duty cycle configurable
  - A duty cycle of 0% to 100% can be configured by means of a duty register.
- Counting clock selectable
  - There is a choice of five counting clocks (P0 $\phi$ , P0 $\phi$ /2, P0 $\phi$ /4, P0 $\phi$ /8, P0 $\phi$ /16).
- High-speed access via internal 16-bit bus
- Two interrupt sources
  - An interrupt can be requested independently for each channel by a cycle register compare match.
- Automatic transfer of register data
  - Block transfer and one-word data transfer are available by activating the direct memory access controller.
- Module stop mode can be set

Figure 52.1 shows a block diagram of the motor control PWM timer.

### 52.3.3 PWM Counter\_n (PWCNT\_n) (n = 1, 2)

PWCNT\_n is a 10-bit up-counter incremented by the input clock. The input clock is selected by clock select bits CKS2 to CKS0 in PWCR\_n.

PWCNT\_n can not be directly accessed by the CPU. PWCNT\_n is initialized to H'FC00, when the CST bit in PWCR\_n is cleared to 0.

### 52.3.4 PWM Cycle Register\_n (PWCYR\_n) (n = 1, 2)

PWCYR\_n is a 16-bit readable/writable register that sets the PWM conversion cycle.

When a PWCYR\_n compare match occurs, PWCNT\_n is cleared and data is transferred from the buffer register (PWBFR\_n) to the duty register (PWDTR\_n).

PWCYR\_n should be written to only while PWCNT\_n is stopped. A value of H'FC00 must not be set to PWCYR\_n.

### 52.3.5 PWM Duty Registers\_nA, nC, nE, nG (PWDTR\_nA, PWDTR\_nC, PWDTR\_nE, PWDTR\_nG) (n = 1, 2)

There are four PWDTR\_n registers (PWDTR\_nA, PWDTR\_nC, PWDTR\_nE, and PWDTR\_nG). The PWDTR\_nA is used for outputs PWMnA and PWMnB, PWDTR\_nC for outputs PWMnC and PWMnD, PWDTR\_nE for outputs PWMnE and PWMnF, and PWDTR\_nG for outputs PWMnG and PWMnH.

PWDTR\_n can not be directly accessed by the CPU. When a PWCYR\_n compare match occurs, data is transferred from the buffer register (PWBFR\_n) to the duty register (PWDTR\_n). PWDTR\_n is initialized to H'00 when the CST bit is cleared to 0.

## 52.4 Bus Master Interface

### 52.4.1 16-Bit Data Registers

PWCYR\_n and PWBFR\_n are 16-bit registers. These registers are linked to the bus master by a 16-bit data bus, and can be read or written in 16-bit units. They cannot be read or written by 8-bit access; 16-bit access must always be used.

Figure 52.5 16-Bit Register Access Operation (Bus Master ↔ PWCYR\_n (16 Bits))

### 52.4.2 8-Bit Data Registers

PWCR\_n, PWPR\_n, and PWBTCR are 8-bit registers that can be read and written to in 8-bit units. These registers are linked to the bus master by a 16-bit data bus, and can be read or written by 16-bit access; in this case, the lower eight bits are read as H'FF.

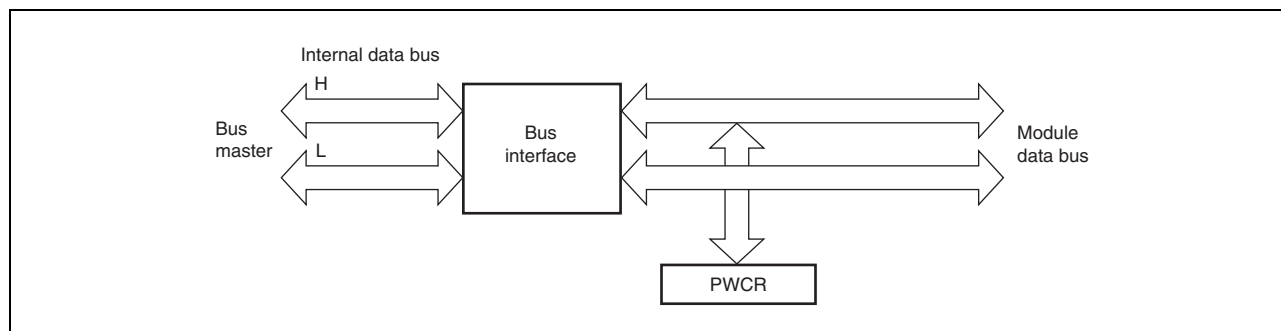

Figure 52.6 8-Bit Register Access Operation (Bus Master ↔ PWCR\_n (Upper Eight Bits))

## 52.5 Operation

### 52.5.1 PWM Operation

PWM waveforms are output from pins PWM1A to PWM1H and PWM2A to PWM2H as shown in Figure 52.7.

#### (1) Initial Settings

Set the PWM output polarity in PWPR\_n; select the clock to be input to PWCNT\_n with the CKS2 to CKS0 bits in PWCR\_n; set the PWM conversion cycle in PWCYR\_n; and set the first frame of data in PWBFR\_nA, PWBFR\_nC, PWBFR\_nE, and PWBFR\_nG.

#### (2) Activation

When the CST bit in PWCR\_n is set to 1, PWCNT\_n starts counting up. On compare match between PWCNT\_n and PWCYR\_n, data is transferred from the buffer register to the duty register and the CMF bit in PWCR\_n is set to 1. At the same time, if the IE bit in PWCR\_n has been set to 1, an interrupt can be requested or the direct memory access controller can be activated.

#### (3) Waveform Output

The PWM outputs selected by the OTS bits in PWDTR\_nA, PWDTR\_nC, PWDTR\_nE, and PWDTR\_nG go high when a compare match occurs between PWCNT\_n and PWCYR\_n. The PWM outputs not selected by the OTS bit are low. When a compare match occurs between PWCNT\_n and PWDTR\_nA, PWDTR\_nC, PWDTR\_nE, or PWDTR\_nG, the corresponding PWM output goes low. If the corresponding bit in PWPR\_n is set to 1, the output is inverted.

**Figure 52.7** PWM Operation

#### (4) Next Frame

When a compare match occurs between PWCNT\_n and PWCYR\_n, data is transferred from the buffer register to the duty register. PWCNT\_n is reset and starts counting up from H'000. The CMF bit in PWCR\_n is set, and if the IE bit in PWCR\_n has been set, an interrupt can be requested or the direct memory access controller can be activated.

#### (5) Stopping

When the CST bit in PWCR\_n is cleared to 0, PWCNT\_n is reset and stops. All PWM outputs go low (or high if the corresponding bit in PWPR\_n is set to 1).

### 52.5.2 Buffer Transfer Control

Setting a corresponding bit in the PWM buffer transfer control register disables a buffer transfer on compare match. This prevents the output from changing when compare match occurs while the buffer register is being changed. A buffer transfer on compare match is resumed after cleaning the bit.

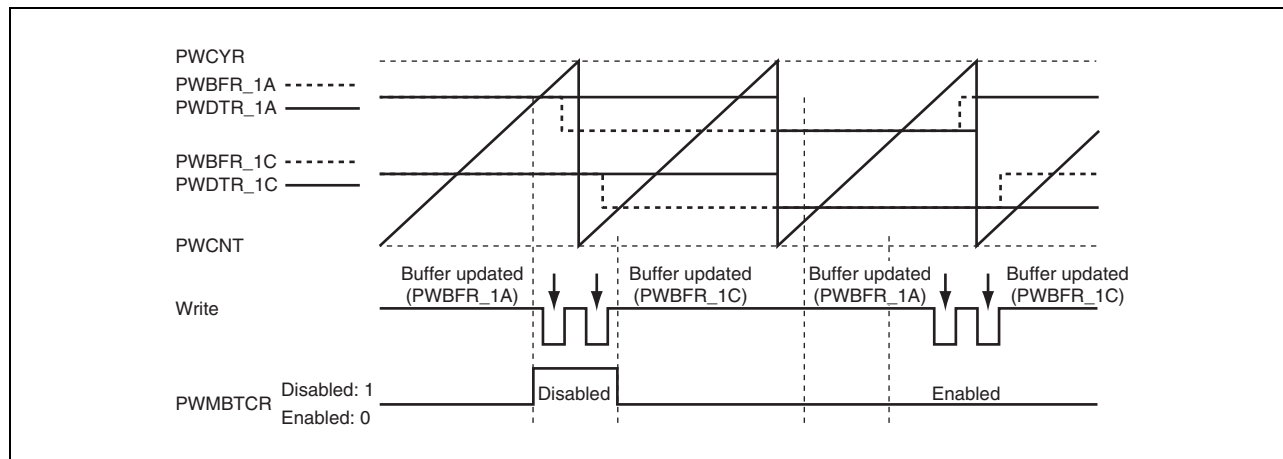

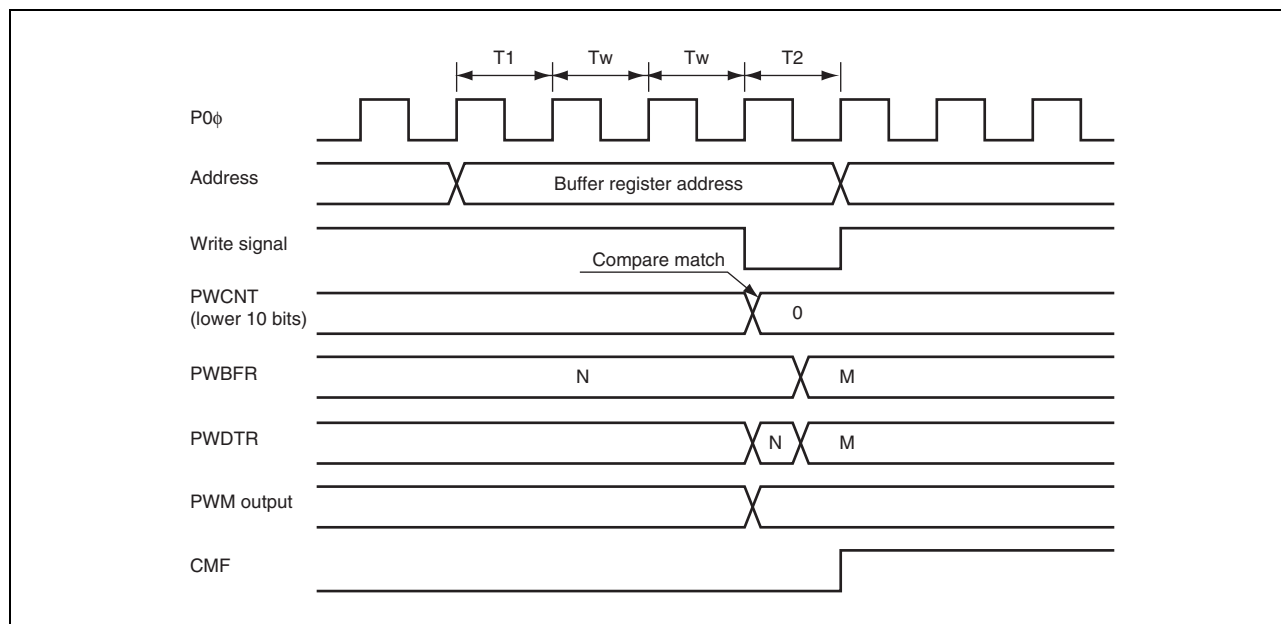

Figure 52.8 Disabling Buffer Transfer

## 52.6 Usage Note

### 52.6.1 Conflict between Buffer Register Write and Compare Match

If a PWBFR\_n write is performed in the state immediately after a cycle register compare match, the buffer register and duty register are both modified. PWM output changed by the cycle register compare match is not changed by modification of the duty register due to conflict. This may result in unanticipated duty output.

Buffer register modification must be completed before automatic transfer by the direct memory access controller, exception handling due to a compare match interrupt, or the occurrence of a cycle register compare match on detection of the rise of CMF (compare match flag) in PWCR\_n.

**Figure 52.9 Conflict between Buffer Register Write and Compare Match**

## 53. On-Chip RAM

This LSI has an on-chip large-capacity RAM for display area and work area (128 Kbytes of this RAM are shared with the on-chip data retention RAM) and an on-chip data retention RAM, which can retain data in deep standby mode. These memory units can be used to store instructions or data.

The operation and write access to the large-capacity RAM (including on-chip data retention RAM) can be enabled or disabled through the RAM enable bits and RAM write enable bits.

The on-chip data retention RAM is assigned to page 0 in the on-chip large-capacity RAM. Retention or non-retention of data by the on-chip data retention RAM in deep standby mode is selectable on a per-page basis.

### 53.1 Features

- Page

- The on-chip large-capacity RAM consists of five pages.
- The on-chip data retention RAM consists of four pages. Page 0 has 16-Kbytes, page 1 has 16-Kbytes, page 2 has 32-Kbytes, and page 3 has 64-Kbytes.

- Memory map

The on-chip RAM is located in the address spaces shown in tables 47.1 to 47.3. Each page of the large-capacity RAM in products with a 10-Mbyte on-chip RAM has a capacity of 2 Mbytes, while each page of the large-capacity RAM in products with a 5-Mbyte on-chip RAM has a capacity of 1 Mbyte. Except for the size, the address maps for products with a 5-Mbyte on-chip RAM and with a 10-Mbyte on-chip RAM are compatible. Furthermore, to obtain a continuous address space for 5-Mbyte RAM compatibility when a 10-Mbyte RAM is in use, each page of the latter is divided into two. If you wish to use the pages continuously when using a 10-Mbyte RAM, use mirror addresses.

- Ports

Each page of the on-chip large-capacity RAM has one read and write port and is connected to the AXI bus. The on-chip RAM for data retention, which has a port independent of the port in page 0, is shared with the read and write port in four pages.

- Method of arbitration

When the same port of the on-chip large-capacity RAM is accessed from different masters simultaneously, the AXI bus performs arbitration in round-robin mode.

- Number of access cycles

The number of cycles for access to read or write is one cycle of  $B\phi$ .

## 53.2 Usage Notes

### 53.2.1 Page Conflict

When the same page of the on-chip large-capacity RAM is accessed from different masters simultaneously, a conflict on the page occurs. Although each access is completed correctly, this kind of conflict degrades the memory access speed. Therefore, it is advisable to provide software measures to prevent such conflicts as far as possible. For example, no conflict will arise if different pages are accessed by each master.

### 53.2.2 Data Retention

Data in the large-capacity RAM (including on-chip data retention RAM) are retained in the states other than power-on reset and deep standby mode. In power-on reset and deep standby mode, these RAMs operate as described below.

#### (1) Power-on Reset

##### (a) On-Chip Large-Capacity RAM (Excluding On-Chip Data Retention RAM)

Data are retained on a power-on reset by disabling the setting of either the VRAME or VRAMWE bit. Data are not retained when the setting of the VRAME and VRAMWE bits are both enabled.

##### (b) On-Chip Data Retention RAM

Data are retained on a power-on reset by disabling the setting of any of the VRAME, VRAMWE, or RRAMWE, excluding the case that deep standby mode is canceled by power-on reset. Data are not retained when the setting of the VRAME, VRAMWE and RRAMWE bits are all enabled.

#### (2) Deep Standby Mode

##### (a) On-Chip Large-Capacity RAM (Excluding On-Chip Data Retention RAM)

Data are not retained.

##### (b) On-Chip Data Retention RAM

Data are retained in deep standby mode by enabling the setting of the RRAMKP bit, excluding the case that deep standby mode is canceled by power-on reset. In the case that deep standby mode is canceled by interrupt or pins for cancelling, power-on reset exception handling is executed, but the data are retained.

## 54. Ports

### 54.1 Features

The 256-pin version of this LSI has eleven ports (JP0 and P0 to P9) and the 324-pin version has thirteen ports (JP0 and P0 to P11). All port pins are multiplexed with other peripheral module pin functions, and by setting the control registers, multiplexed pin functions (alternative functions) can be selected.

#### 54.1.1 Port group

This LSI has the following number of port groups.

**Table 54.1 Port Group**

Package	Number	Name
RZ/A1H 256-pin	11	P0 to P9, JP0
RZ/A1H 324-pin	13	P0 to P11, JP0

#### 54.1.2 Port group index n

Throughout this section, the individual port groups are identified by the index "n" (n = 0 to 11), for example PMCN for the port mode control register, which is used for the Pn pin.

#### 54.1.3 Base address

The addresses of the registers used to control the JTAG ports are given as addresses offset from the base address <JPORTn\_base>. The addresses of the other registers used to control the general ports are given as addresses offset from the base address <PORTn\_base>.

**Table 54.2 Base Addresses <PORTn\_base> and <JPORTn\_base>**

## 54.2 Functional Overview

### 54.2.1 Mode of Pin Functions

Pins can operate in three modes.

Port mode (PM<sub>Cn</sub>.PM<sub>Cnm</sub> bit = 0)

A pin in port mode operates as a general purpose input/output pin. The I/O mode is selected by setting the PM<sub>n</sub>.PM<sub>nm</sub> bit.

Software I/O control alternative mode (PM<sub>Cn</sub>.PM<sub>Cnm</sub> bit = 1, PIP<sub>Cn</sub>.PIP<sub>Cnm</sub> bit = 0)

In this mode, the pins operate as alternative functions.

The I/O mode is selected by setting the PM<sub>n</sub>.PM<sub>nm</sub> bit by using software.

Direct I/O control alternative mode (PM<sub>Cn</sub>.PM<sub>Cnm</sub> bit = 1, PIP<sub>Cn</sub>.PIP<sub>Cnm</sub> bit = 1)

In this mode, the pins operate as alternative functions.

Unlike the software I/O alternative mode, however, the I/O mode is selected by the alternative function.

An overview of the register settings is given in the tables below.

**Table 54.3 Pin Function Configuration (Overview)**

Mode	Bit			I/O
	PM <sub>Cn</sub> . PM <sub>Cnm</sub>	PM <sub>n</sub> . PM <sub>nm</sub>	PIP <sub>Cn</sub> . PIP <sub>Cnm</sub>	
Port mode	0	0	X	O
		1*1		I
Software I/O control alternative mode	1*2	0	0	O
		1		I
Direct I/O control alternative mode		X	1	Controlled by the alternative function

Note 1. The input buffer can be enabled in the port mode only when the PIB<sub>Cn</sub>.PIB<sub>Cnm</sub> bit is set to 1.

Note 2. When the pins are in alternative mode (PM<sub>Cn</sub>.PM<sub>Cnm</sub> = 1), one of the eight alternative functions is selected by the PFC<sub>n</sub>, PFC<sub>En</sub>, and PFCA<sub>En</sub> registers. For details, see Table 54.6, Alternative Mode Selection\*2.

## 54.2.2 Pin Data Input/Output

The registers used for data input/output are described below. The location that is read via the PPRn register differs depending on the pin mode.

- Output data

In the port mode (PMcn.PMCnm = 0), the value of the Pn.Pnm bit is output from the Pn\_m pin.

- Input data

When the PPRn register is read, either the value of the Pn\_m pin, the value of the Pn.Pnm bit, or the value output by the alternative function is returned. Which value is returned depends on the pin mode and setting of several control bits. The different PPRn read values are shown in the table below.

**Table 54.4 PPRnm Read Values**

PMcn. PMcnm	PMn. PMnm	PIBCn. PIBCnm	PIPCn. PIPCnm	Mode	PPRnm Read Value
0	1	0	X	Port input, input buffer disabled	Pn.Pnm register
		1		Port input, input buffer enabled	Pn_m pin
	0	X	Port output	Pn.Pnm register*1	
1	1	X	0	Software I/O control alternative function input	Pn_m pin
	0			Software I/O control alternative function output	Alternative-function internal output signal*1
	X		1	Direct I/O control alternative function	I/O port in alternative mode: • Input: Pn_m pin • Output: Alternative-function internal output signal*1

Note 1. When the PBDCn.PBDCnm bit is 1, the level of the Pn\_m pin is returned by the PPRn.PPRnm bit.

### 54.3 Register Description

The following registers are used for setting the individual pins of the port groups:

#### 54.3.1 Port Register (Pn)

In output port mode (PMCn.PMCnm = 0 and PMn.PMnm = 0), this register holds the Pn.Pnm data to be output via the Pn\_m pin.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Pn15	Pn14	Pn13	Pn12	Pn11	Pn10	Pn9	Pn8	Pn7	Pn6	Pn5	Pn4	Pn3	Pn2	Pn1	Pn0

### 54.3.2 Port Set and Reset Register (PSRn)

This register provides an alternative method for writing data to the Pn register.

The higher 16 bits of the PSRn register specify whether data can be written to the Pn.Pnm bit specified by the lower 16 bits of the PSRn register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PSRn 31	PSRn 30	PSRn 29	PSRn 28	PSRn 27	PSRn 26	PSRn 25	PSRn 24	PSRn 23	PSRn 22	PSRn 21	PSRn 20	PSRn 19	PSRn 18	PSRn 17	PSRn 16

Bit Position	Bit Name	Function
31 to 16	PSRn[31:16]	These are enable bits that specify whether the value of the corresponding lower bit of the PSRn.PSRnm bits is written to the corresponding Pn.Pnm bit. 0: Pn.Pnm is independent of PSRn.PSRnm 1: Pn.Pnm becomes the value of the PSRn.PSRnm bit. Example: If PSRn.PSRn31 = 1, the value of PSRn.PSRn15 is written to Pn.Pn15.
15 to 0	PSRn[15:0]	These are data bits that specify the value of the Pn.Pnm bit if the corresponding higher bit, PSRn.PSRn (m+16), is 1. 0: Pn.Pnm = 0 1: Pn.Pnm = 1

### 54.3.3 Port Pin Read Register (PPRn/JPPR0)

The PPRn register reflects either the level of the Pn\_m pin, the value of the Pn.Pnm bit, or the output level of the alternative function. The value read depends on various register settings as described in Table 54.4, PPRnm Read Values.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PPRn 15	PPRn 14	PPRn 13	PPRn 12	PPRn 11	PPRn 10	PPRn9 9	PPRn8 8	PPRn7 7	PPRn6 6	PPRn5 5	PPRn4 4	PPRn3 3	PPRn2 2	PPRn1 1	PPRn0 0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit Position	Bit Name	Function
15 to 0	PPRn[15:0]	The value of the Pn_m pin, the value of the Pn.Pnm bit, or the output level of the alternative function.

- Notes:
1. For the PPRn register read value, see section 54.2.2, Pin Data Input/Output.
  2. The JPPR0[1:0] bits are control bits in the JTAG port pin read register (JPPR0).

### 54.3.4 Port Mode Register (PMn)

The PMn register specifies whether the Pn\_m pins are in input mode or in output mode.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PMn	PMn	PMn	PMn	PMn	PMn	PMn9	PMn8	PMn7	PMn6	PMn5	PMn4	PMn3	PMn2	PMn1	PMn0
	15	14	13	12	11	10										
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit Position	Bit Name	Function
15 to 0	PMn[15:0]	Specifies input/output mode of the corresponding pin: 0: Output mode (output enabled) 1: Input mode (output disabled)

- Notes:
1. To use the Pn\_m pin in input port mode (PMCn.PMCnm = 0 and PMn.PMnm = 1), the input buffer must be enabled by setting the PIBCn.PIBCnm bit to 1.
  2. After reset is issued, the PIPCn.PIPCnm bit is set to 0 and the PMn.PMnm bit specifies the I/O direction for port mode (PMCn.PMCnm = 0) and alternative mode (PMCn.PMCnm = 1). For the pins whose functions are automatically selected in boot mode (see Table 8.3, Initial States by Areas in Boot Modes 0, 1, and 2 to 5), the I/O direction is controlled by the alternative functions instead of the PMn register.

### 54.3.5 Port Mode Control Register (PMCn/JPMC0)

This register is used to specify whether the Pn\_m pins are in port mode or in alternative mode.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PMCn	PMCn	PMCn	PMCn	PMCn	PMCn	PMCn	PMCn	PMCn	PMCn	PMCn	PMCn	PMCn	PMCn	PMCn	PMCn
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit Position	Bit Name	Function
15 to 0	PMCn[15:0]	Specifies the operation mode of the corresponding pin: 0: Port mode 1: Alternative mode

Caution: The input/output control is not performed just by setting alternative mode (PMCn.PMCnm). Set 1 in the PIPCn.PIPCnm bit too when the I/O control is to be performed by using the alternative function.

Note: The JPMC0[1:0] bits are control bits in the JTAG port mode control register (JPMC0).

### 54.3.6 Port Function Control Register (PFCn)

This register, together with the PFCEn and PFCAEn register, specifies the alternative function of the pins.

The I/O direction of several alternative functions can be controlled directly by using the Pn\_m pin. For these alternative functions, the PIPCN.PIPCnm bit must be set to 1.

For all other alternative functions, the I/O direction is specified by using the PMn.PMnm bit.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PFCn 15	PFCn 14	PFCn 13	PFCn 12	PFCn 11	PFCn 10	PFCn9	PFCn8	PFCn7	PFCn6	PFCn5	PFCn4	PFCn3	PFCn2	PFCn1	PFCn0

Bit Position	Bit Name	Function
15 to 0	PFCn[15:0]	Specifies the alternative function of a pin.

						0	Alternative mode/7th alternative function/output
		1	0	0	1	1	Alternative mode/8th alternative function/input
						0	Alternative mode/8th alternative function/output

Note 1. When the PIPCN.PIPCnm bit is set to 1, the I/O direction is directly controlled by the alternative function and the setting of the PMn.PMnm bit becomes invalid.

Note 2. Use alternative functions that are open to users. If a mode to which no alternative function is assigned is selected, correct operation is not guaranteed.

### 54.3.7 Port Function Control Expansion Register (PFCEn)

This register, together with the PFCn and PFCAEn register, specifies the alternative function of the pins.

The I/O direction of several alternative functions can be controlled directly by using the Pn\_m pin. For these alternative functions, the PIPCn.PIPCnm bit must be set to 1.

For all other alternative functions, the I/O direction is specified by using the PMn.PMnm bit.

### 54.3.9 Port Mode Set and Reset Register (PMSRn)

This register provides an alternative method for writing data to the PMn register.

The higher 16 bits of the PMSRn register specify whether data can be written to the PMn.PMnm bit specified by the lower 16 bits of the PMSRn register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### 54.3.10 Port Mode Control Set and Reset Register (PMCSRn/JPMCSR0)

This register provides an alternative method for writing data to the PMCn register.

The higher bits of the PMCSRn register specify whether data can be written to the PMCn.PMCnm bit specified by the lower bits of the PMCSRn register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 16	PMCSRn[31:16]	These are enable bits that specify whether the value of the corresponding lower bit of the PMCSRn.PMCn bits is written to the corresponding PMCn.PMCnm bit. 0: PMCn.PMCnm does not depend on the PMCSRn.PMCn bit. 1: PMCn.PMCnm becomes the value of the PMCSRn.PMCn bit. Example: If PMCSRn.PMCn31 = 1, the value of PMCSRn.PMCn15 is written to PMCn.PMCn15.
15 to 0	PMCSRn[15:0]	These are data bits that specify the value of the PMCn.PMCnm bit if the corresponding higher bit, PMCSRn.PMCn(m+16), is 1. 0: PMCn.PMCnm = 0 1: PMCn.PMCnm = 1

Note: The JPMCSR0[1:0] bits are control bits in the JTAG port mode control set/reset register (JPMCSR0).

### 54.3.11 Port Function Control Additional Expansion Register (PFCAEn)

This register, together with the PFCn and PFCEn register, specifies the alternative function of the pins.

The I/O direction of several alternative functions can be controlled directly by using the Pn\_m pin. For these alternative functions, the PIPCN.PIPCNm bit must be set to 1.

For all other alternative functions, the I/O direction is specified by using the PMn.PMnm bit.

After selecting an alternative function by the PFCn.PFCnm, PFCEn.PFCEnm, or PFCAEn.PFCAEnm bit, set the PMCn.PMCnm bit to 1.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PFCAE n15	PFCAE n14	PFCAE n13	PFCAE n12	PFCAE n11	PFCAE n10	PFCAE n9	PFCAE n8	PFCAE n7	PFCAE n6	PFCAE n5	PFCAE n4	PFCAE n3	PFCAE n2	PFCAE n1	PFCAE n0

Bit Position	Bit Name	Function
15 to 0	PFCAEn[15:0]	Specifies the alternative function of a pin.

Caution: Although some alternative functions are assigned to multiple pins in this LSI, only one of the pins can be used for each alternative function. Do not set the same alternative function in multiple pins. For example, when the a/b/c pin is used as the b pin, the b/d/e pin cannot be used as the b pin. Before using the b/d/e pin, set the pin as an alternative function other than b.

Note: For the allocation of the alternative functions, see the table of the pin functions of each port.

### 54.3.12 Port Input Buffer Control Register (PIBCn)

In input port mode ( $PMn.PMCnm = 0$  and  $PMn.PMnm = 1$ ), this register enables or disables the input buffer for the  $Pn\_m$  pin.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIBCn 15	PIBCn 14	PIBCn 13	PIBCn 12	PIBCn 11	PIBCn 10	PIBCn 9	PIBCn 8	PIBCn 7	PIBCn 6	PIBCn 5	PIBCn 4	PIBCn 3	PIBCn 2	PIBCn 1	PIBCn 0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit Position	Bit Name	Function
15 to 0	PIBCn[15:0]	These bits enable or disable the input buffer. 0: Input buffer disabled 1: Input buffer enabled

Note: When the input buffer is disabled, through current does not flow even when the pin level is Hi-Z. Thus the pin does not need to be fixed to a high or low level externally (except for P2\_12, P2\_15, P3\_1, P3\_3, P3\_9, P5\_09, P6\_2, P6\_4, P7\_8, P8\_02, P8\_7, and P9\_1).

Caution: When the output buffer is enabled and the PBDCn.PBDCnm bit is 1, the input buffer is enabled regardless of this register setting.

### 54.3.13 Port Bidirection Control Register (PBDCn/JPBDC0)

This register enables or disables the input buffer while the output buffer is enabled. When the input buffer is enabled while the output buffer is enabled, the bidirectional mode is entered, allowing the level of the  $Pn\_m$  pin to always be read via the PPRn.PPRnm bit.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PBDCn 15	PBDCn 14	PBDCn 13	PBDCn 12	PBDCn 11	PBDCn 10	PBDCn 9	PBDCn 8	PBDCn 7	PBDCn 6	PBDCn 5	PBDCn 4	PBDCn 3	PBDCn 2	PBDCn 1	PBDCn 0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit Position	Bit Name	Function
15 to 0	PBDCn[15:0]	Enables/disables bidirectional mode of the corresponding pin: 0: Bidirectional mode disabled 1: Bidirectional mode enabled

Caution: When using the  $Pn\_m$  bit as the output of an alternative function ( $PMn.PMCnm = 1$ ,  $PMn.PMnm = 0$ ), the level of the  $Pn\_m$  pin can be read at the PPRn.PPRnm bit by setting the PBDCn.PBDCnm bit to 1. Note, however, that in this case, the level of the  $Pn\_m$  pin will be conveyed to the input of the alternative function that the  $Pn\_m$  pin is being used as.

Note: The JPBDC0[1:0] bits are control bits in the JTAG port bidirection control register (JPBDC0).

### 54.3.14 Port IP Control Register (PIPCn)

This register is used to specify whether the I/O direction of the Pn\_m pin is controlled by the PMn.PMnm bit or by the alternative function in alternative mode (the PMCn.PMCnm bit is 1).

When using an alternative function shown in Table 54.7, set the PIPCn.PIPCnm bit to 0. When using an alternative function that is not shown in Table 54.7, set the PIPCn.PIPCnm bit to 1. When the PIPCn.PIPCnm bit is set to 1, the alternative function controls the I/O direction and the PMn.PMnm bit setting becomes invalid.

Bit Position	Bit Name	Function
15 to 0	PIPCn[15:0]	These bits specify how to control the I/O direction in alternative mode. 0: The I/O direction is controlled according to the value of the PMn.PMnm bit (software I/O control). 1: The I/O direction is controlled by the alternative function (direct I/O control).

### 54.3.15 Serial Sound Interface Noise Canceler Control Register (SNCR)

This register controls the noise canceler in the input route from the LSI pin to a serial sound interface. Each bit can be set only when slave mode is selected for the corresponding channel of the serial sound interface. The bit should be used as it is the initial value (H'00000000) when master mode is selected for the corresponding channel of the serial sound interface.

### 54.18 Port Control Logical Diagram

The following shows a logical diagram of the port control function.

Note: This figure shows the logic for reference, not the circuit.

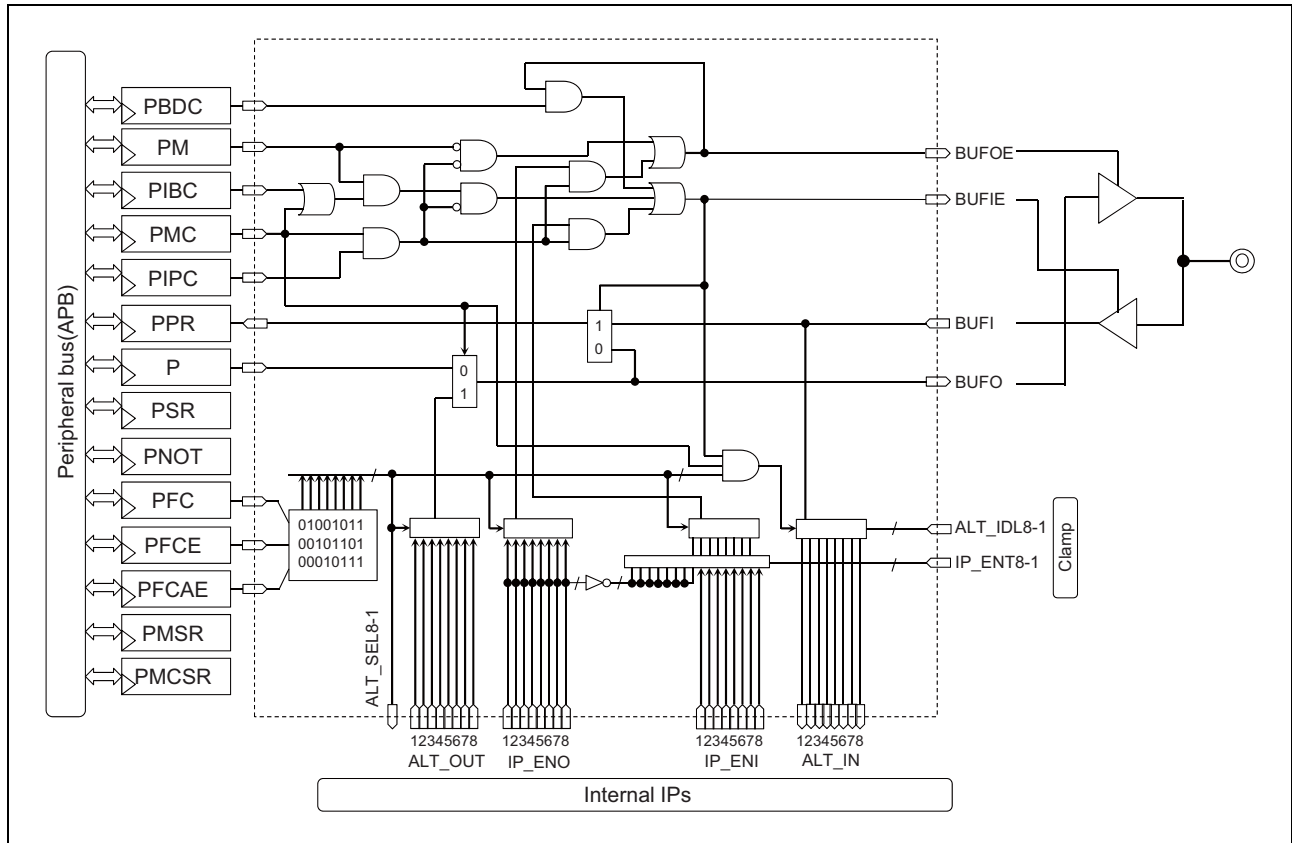

Figure 54.1 Logical Diagram of Port Control

## 54.19 Flowchart Examples of Port Setting

A flowchart example for setting the Pn\_m pin to port mode is shown in (a), an example for setting software I/O control alternative mode is shown in (b), and an example for setting direct I/O control alternative mode is shown in (c).

### (a) Port settings for port mode

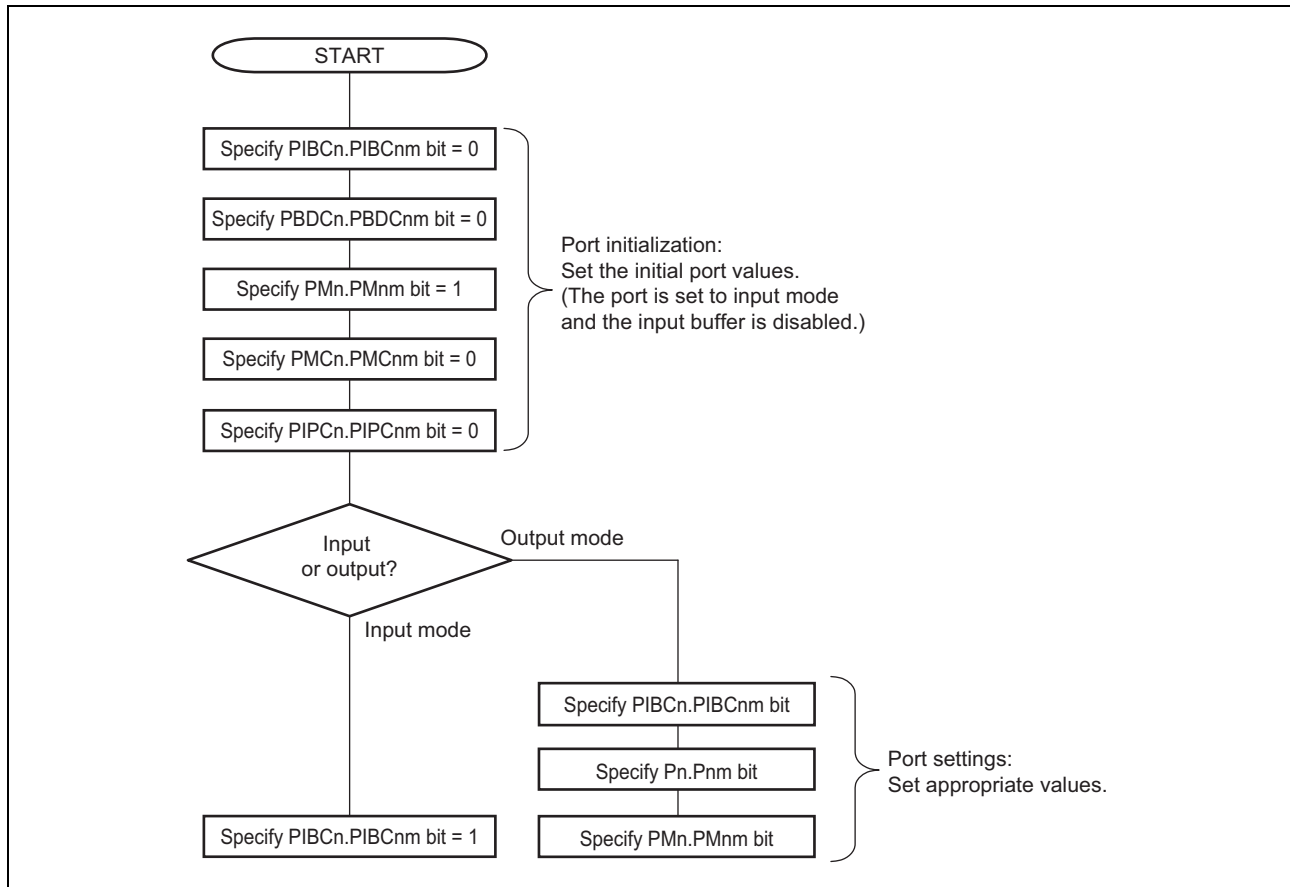

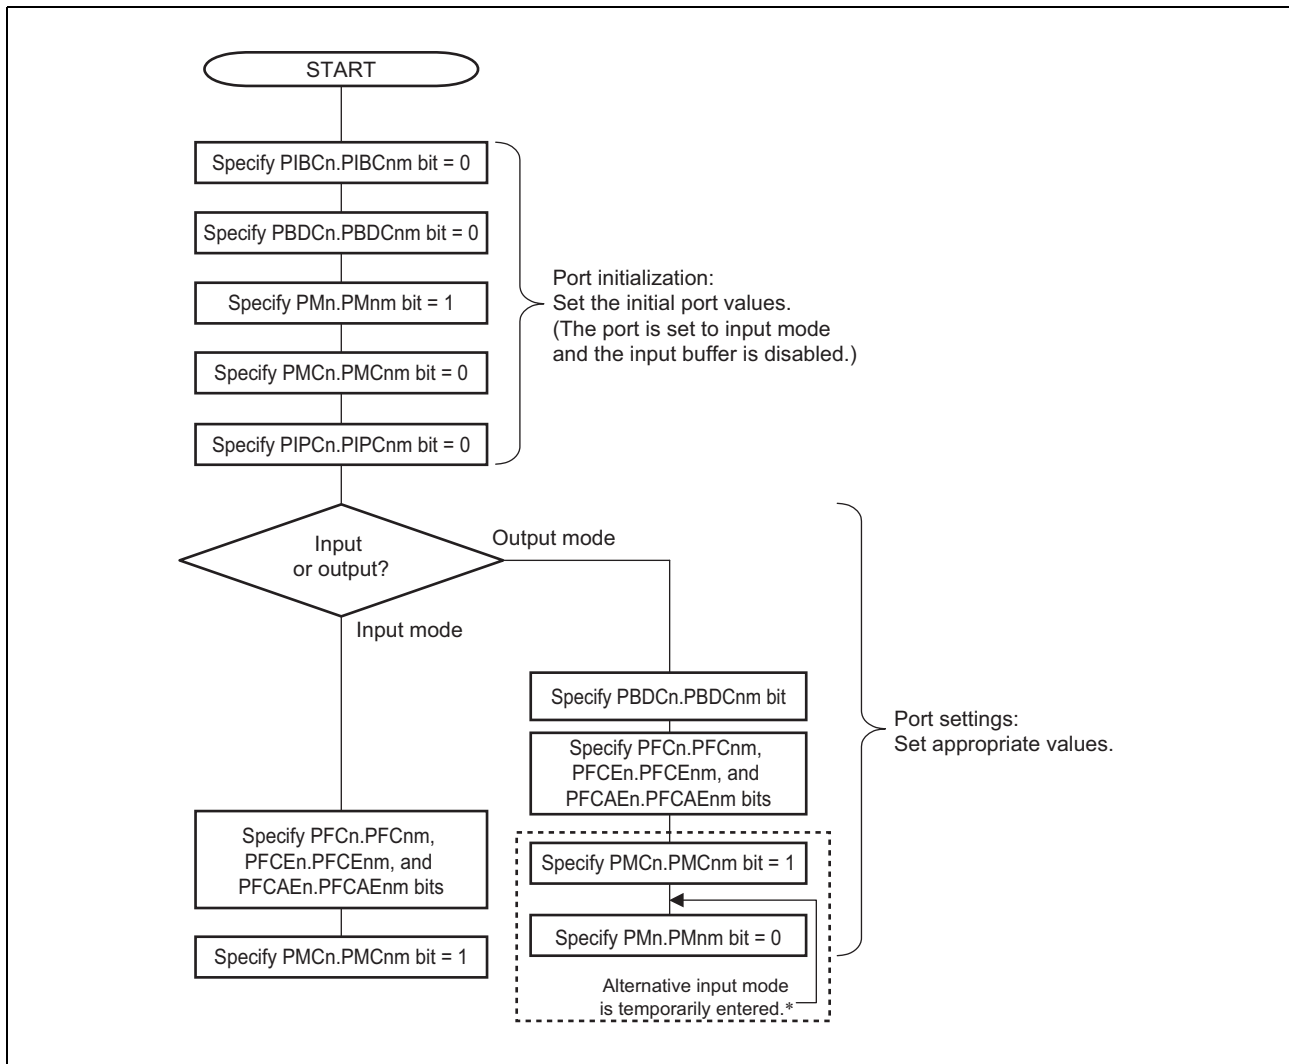

Figure 54.2 Example of Port Settings (in Port Mode) (1/3)

## (b) Port settings for software I/O control alternative mode

**Figure 54.3 Example of Port Settings (in Software I/O Control Alternative Mode) (2/3)**

**Note:** When the Pn\_m pin is set to the output mode in software I/O control alternative mode, the alternative input mode is temporarily entered after the PMCn.PMCnm bit is set to 1 until the PMn.PMnm bit is cleared to 0. Therefore, when an interrupt-related signal is selected as the alternative function for the port pin, appropriate settings should be made so that the interrupt does not occur or is ignored.

## 55. Power-Down Modes

This LSI supports sleep mode, software standby mode, deep standby mode, and module standby mode. In power-down modes, functions of CPU, clocks, on-chip memory, or part of on-chip peripheral modules are halted or the power-supply is turned off, through which low power consumption is achieved. These modes are canceled by a reset or interrupt.

### 55.1 Features

#### 55.1.1 States of Processing and Power-Down Modes

##### (1) States of processing

This LSI has three general states of processing: the reset state, the program execution state, and the power-down modes. Figure 55.1 shows transitions between these states.

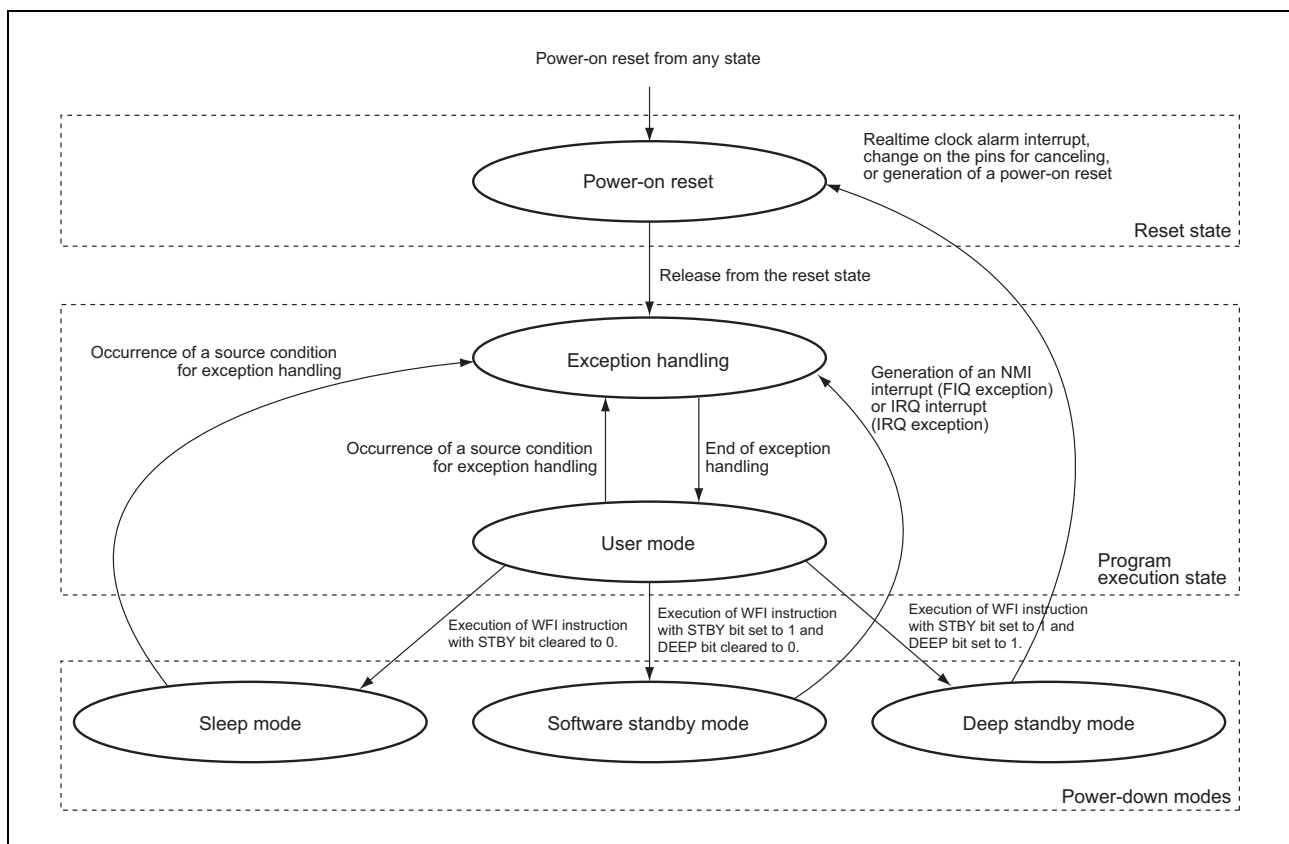

Figure 55.1 Transitions between Processing States

##### (2) Power-down modes

This LSI has the following power-down modes and function:

1. Sleep mode
2. Software standby mode
3. Deep standby mode
4. Module standby function

Table 55.1 shows the transition conditions for entering the modes from the program execution state, as well as the CPU and peripheral module states in each mode and the procedures for canceling each mode.

Table 55.1 States of Power-Down Modes

Power-Down Mode	Transition Conditions	State							
		CPU, CPU Register, Primary Cache, TLB	Secondary Cache	Large-Capacity On-Chip RAM (including on-chip data-retention RAM)	On-Chip Peripheral Modules	Realtime Clock	Internal Power Supply	External Memory	Canceling Procedure
Sleep mode	Execute WFI instruction with STBY bit in STBCR1 cleared to 0	Halted Contents are held.*4	Running	Running	Running	Running*1	Applied	Auto-refresh	<ul style="list-style-type: none"> <li>Interrupt</li> <li>Power-on reset</li> </ul>
Software standby mode	Execute WFI instruction with STBY and DEEP bits in STBCR1 set to 1 and 0, respectively	Halted Contents are held.*4	Halted Contents are held.*4	Halted Contents are held.*5	Halted	Running*1	Applied	Self-refresh	<ul style="list-style-type: none"> <li>NMI or IRQ interrupt</li> <li>Power-on reset</li> </ul>
Deep standby mode	Execute WFI instruction with STBY and DEEP bits in STBCR1 set to 1	Halted Contents are not held.	Halted Contents are not held.	Halted Contents in on-chip data-retention RAM are held*2, and the other contents in large-capacity on-chip RAM are not held.	Halted	Running*1	Shut off	Self-refresh	<ul style="list-style-type: none"> <li>Power-on reset*3</li> <li>Realtime clock alarm interrupt*3</li> <li>Change on the pins for canceling*3</li> </ul>
Module standby mode	Set the MSTP bits in STBCR2 to STBCR13 to 1	Running	Running	Running	Specified module halted	Halted	Applied	Auto-refresh	<ul style="list-style-type: none"> <li>Clear MSTP bit to 0</li> </ul>

Note 1. The realtime clock operates when the START bit in the RCR2 register is set to 1. For details, see section 13, Realtime Clock. When deep standby mode is canceled by a power-on reset, the running state cannot be retained. Make the initial setting for the realtime clock again.

Note 2. Setting the bits RRAMKP3 to RRAMKP0 in the RRAMKP register to 1 enables to retain the data in the corresponding area on the on-chip data-retention RAM during the transition to deep standby mode. When the deep standby mode is canceled by a power-on reset, the retained contents are initialized.

Note 3. Deep standby mode can be canceled by a power-on reset, a realtime clock alarm interrupt, or change on the pins for canceling (P2\_12, P2\_15, P3\_1, P3\_3, P3\_9, P5\_9, P6\_2, P6\_4, P7\_8, P8\_2, P8\_7, P9\_1, and NMI). Even when deep standby mode is canceled by a source other than a power-on reset, the reset exception handling is executed instead of the interrupt exception handling.

Note 4. When sleep mode or software standby mode is canceled by a power-on reset, the retained contents are initialized.

Note 5. By setting the VRAME bit in the SYSCR1 register or VRAMWE bit in the SYSCR2 register to enable accesses, the retained contents are initialized when software standby mode is canceled by a power-on reset. By setting the VRAME bit in the SYSCR1 register or VRAMWE bit in the SYSCR2 register to disable accesses, contents in the large-capacity on-chip RAM (including on-chip data-retention RAM) can be retained when software standby mode is canceled by a power-on reset. Note that the area at addresses from H'2002\_0000 to H'2002\_3FFF is used as working memory for the boot program in boot modes 3 to 5. In boot modes 4 and 5, a 28-Kbyte program is transferred from the external flash memory to the area at addresses from H'2002\_4000 to H'2002\_AFFF. For details, see section 3, Boot Mode.

### 55.2.29 Deep Standby Cancel Source Flag Register (DSFR)

DSFR is a 16-bit readable/writable register composed of two types of bits. One is the flag that confirms which source canceled deep standby mode. The other is the bit that releases the state of pins after canceling deep standby mode. When deep standby mode is canceled by an interrupt (NMI, realtime clock alarm interrupt, or change on the pins for canceling) and changes on the pins for canceling, this register retains the previous data although power-on reset exception handling is executed. When deep standby mode is canceled by a power-on reset, this register is initialized to H'0000.

All flags must be cleared immediately before transition to deep standby mode.

Note: • When writing to this register, see section 55.4, Usage Notes.

XTALCTR is an 8-bit readable/writable register that controls the gain of the crystal oscillator for XTAL and the realtime clock.

If the realtime clock uses the EXTAL input, the GAIN0 bit retains the previous value when software standby mode or deep standby mode is canceled by a source other than a power-on reset. If the realtime clock does not use the EXTAL input, this bit is initialized to 0 when software standby or deep standby mode is entered.

If the realtime clock uses the RTC\_X1 or RTC\_X3 input, the GAIN1 bit retains the previous value when software standby mode or deep standby mode is canceled by a source other than a power-on reset. If the realtime clock does not use the RTC\_X1 or RTC\_X3 input, this bit is initialized to 0 when software standby or deep standby mode is entered.

This bit is initialized to H'00 when software standby or deep standby mode is canceled by a power-on reset.

Note: • When writing to this register, see section 55.4, Usage Notes.

## 55.3 Operation

### 55.3.1 Sleep Mode

#### (1) Transition to Sleep Mode

Executing the WFI instruction when the STBY bit in STBCR1 is 0 causes a transition from the program execution state to sleep mode. Although the CPU halts immediately after executing the WFI instruction, the contents of its internal registers remain unchanged. The on-chip peripheral modules continue to run in sleep mode. The clock output from the CKIO pin is continued.

#### (2) Canceling Sleep Mode

Sleep mode is canceled by an interrupt (NMI, IRQ, and on-chip peripheral module) or a power-on reset.

- Canceling by an interrupt  
When an NMI, IRQ, or on-chip peripheral module interrupt occurs, sleep mode is canceled and interrupt exception handling is executed. When the priority level of the generated interrupt is lower than the setting of the interrupt controller execution priority register, or the interrupt by the on-chip peripheral module is disabled on the module side, the interrupt request is not accepted and sleep mode is not canceled. When an interrupt request occurs with an interrupt masked by bits 6 (the FIQ mask bit) and 7 (the IRQ mask bit) in the CPSR register in the CPU, sleep mode is canceled but interrupt exception handling is not executed.
- Canceling by a reset  
Sleep mode is canceled by a power-on reset.

### 55.3.2 Software Standby Mode

#### (1) Transition to Software Standby Mode

The LSI switches from a program execution state to software standby mode by executing the WFI instruction when the STBY bit and DEEP bit in STBCR1 are 1 and 0 respectively. In software standby mode, not only the CPU but also the clock and on-chip peripheral modules halt. The clock output from the CKIO pin also stops.

The contents of the CPU and cache registers remain unchanged. Some registers of on-chip peripheral modules are, however, initialized. As for the states of on-chip peripheral module registers in software standby mode, see section 57.3, Register States.

The CPU takes one cycle to finish writing to STBCR1, and then executes processing for the next instruction. However, it takes one or more cycles to actually write. Therefore, execute a WFI instruction after reading STBCR1 to have the values written to STBCR1 by the CPU to be definitely reflected in the WFI instruction.

The procedure for switching to software standby mode is as follows:

1. Set the standby\_mode\_en bit of the power control register in the PL310 to 1. For the details of this register, see CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual issued by ARM Ltd.
2. Clear the TME bit in the watchdog timer control/status register (WTCSR) of the watchdog timer to 0 to stop the watchdog timer.
3. Set the timer counter (WTCNT) of the watchdog timer to 0 and the CKS[2:0] bits in WTCSR to appropriate values to secure the specified oscillation settling time.
4. After setting the STBY and DEEP bits in STBCR1 to 1 and 0 respectively, read STBCR. Then, execute a WFI instruction.

## (2) Canceling Software Standby Mode

Software standby mode is canceled by interrupts (NMI or IRQ) or a reset (power-on reset). Clock signal starts to be output from the CKIO pin.

- Canceling by an interrupt

When the falling edge or rising edge of the NMI pin (selected by the NMI edge select bit (NMIE) in the interrupt control register 0 (ICR0) of the interrupt controller) or the falling edge or rising edge of an IRQ pin (IRQ7 to IRQ0) (selected by the IRQn sense select bits (IRQn1S and IRQn0S) in interrupt control register 1 (ICR1) of the interrupt controller) is detected, clock oscillation is started. This clock pulse is supplied only to the oscillation settling counter (watchdog timer) used to count the oscillation settling time.

After the elapse of the time set in the clock select bits (CKS[2:0]) in the watchdog timer control/status register (WTCSR) of the watchdog timer before the transition to software standby mode, the watchdog timer overflow occurs. Since this overflow indicates that the clock has been stabilized, the clock pulse will be supplied to the entire chip after this overflow. Software standby mode is thus cleared and NMI interrupt exception handling (IRQ interrupt exception handling in case of IRQ) is started. If the priority level of the generated interrupt is lower than the setting of the interrupt controller execution priority register, the interrupt request is not accepted and sleep mode is entered. So, cancel software standby mode by an interrupt whose priority level is higher than the setting of the interrupt controller execution priority register.

When canceling software standby mode by the NMI interrupt or IRQ interrupt, set the CKS[2:0] bits so that the watchdog timer overflow period will be equal to or longer than the oscillation settling time.

The clock output phase of the CKIO pin may be unstable immediately after detecting an interrupt and until software standby mode is canceled.

- Canceling by a reset

When the RES pin is driven low, software standby mode is canceled and the LSI enters the power-on reset state. After that, if the RES pin is driven high, the power-on reset exception handling is started.

Keep the RES pin low until the clock oscillation settles. The internal clock will continue to be output to the CKIO pin.

## (3) Note on Transition to Software Standby Mode

Release from software standby mode is triggered by interrupts (NMI or IRQ) or a power-on reset. If, however, a WFI instruction and an interrupt other than NMI and IRQ are generated at the same time, software standby mode may be canceled due to acceptance of the interrupt.

When initiating a transition to software standby mode, make settings so that interrupts other than NMI and IRQ are not generated before execution of the WFI instruction.

## (4) Note on Canceling Software Standby Mode

After software standby mode is canceled, unstable clock pulses are output from the CKIO pin during oscillation settling time. To prevent malfunction due to the unstable pulses, the CKOEN[1:0] bits in FRQCR should be modified.

### 55.3.3 Software Standby Mode Application Example

This example describes a transition to software standby mode on the falling edge of the NMI signal, and cancellation on the rising edge of the NMI signal. The timing is shown in Figure 55.2.

When the NMI pin is changed from high to low level while the NMI edge select bit (NMIE) in the interrupt control register 0 (ICR0) is set to 0 (falling edge detection), the NMI interrupt is accepted. When the NMIE bit is set to 1 (rising edge detection) by the NMI exception service routine, the STBY and DEEP bits in STBCR1 are set to 1 and 0 respectively, and a WFI instruction is executed, software standby mode is entered. Thereafter, software standby mode is canceled when the NMI pin is changed from low to high level.

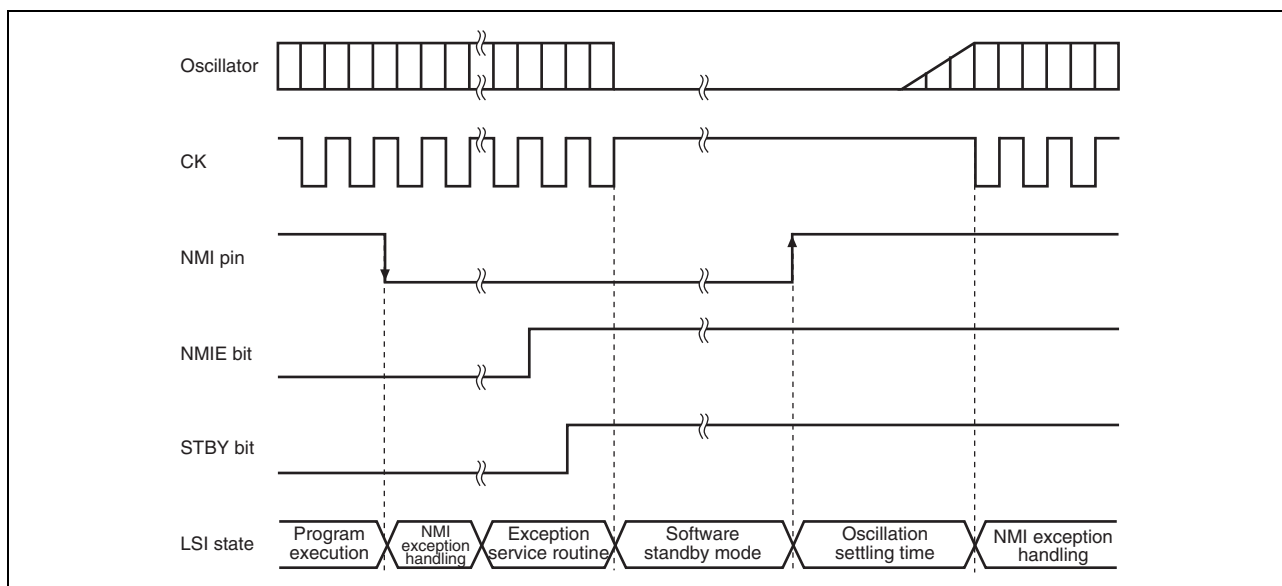

Figure 55.2 NMI Timing in Software Standby Mode (Application Example)

### 55.3.4 Deep Standby Mode

#### (1) Transition to Deep Standby Mode

The LSI switches from a program execution state to deep standby mode by executing the WFI instruction when the STBY bit and DEEP bit in STBCR1 are set to 1. In deep standby mode, not only the CPU, clocks, and on-chip peripheral modules but also power supply is turned off excluding the on-chip data-retention RAM area specified by the RRAMKP3 to RRAMKP0 bits in RRAMKP and realtime clock. This can significantly reduce power consumption. Therefore, data in the registers of the CPU, cache, and on-chip peripheral modules are not retained. Pin state values immediately before the transition to deep standby mode are retained.

The CPU takes one cycle to finish writing to STBCR1, and then executes processing for the next instruction. However, it actually takes one or more cycles to write. Therefore, execute a WFI instruction after reading STBCR1 to reflect the values written to STBCR1 by the CPU in the WFI instruction without fail.

The procedure for switching to deep standby mode is as follows. Figure 55.3 also shows its flowchart.

1. Set the `standby_mode_en` bit of the power control register in the PL310 to 1. For the details of this register, see CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual issued by ARM Ltd.
2. Set the RRAMKP3 to RRAMKP0 bits in RRAMKP for the corresponding on-chip data-retention RAM area that must be retained. Transfer the programs to be retained to the specified areas of the on-chip data-retention RAM.
3. Set the RAMBOOT and EBUSKEEPE bits in DSCTR to specify the activation method for returning from deep standby mode and to select whether the external memory control pin status is retained or not.
4. When canceling deep standby mode by an interrupt, set the corresponding bit in DSSSR to select the pin or source to cancel deep standby mode. In this case, specify the input signal detection mode for the selected pin with the

corresponding bit in DSESR.

5. Execute read and write of an arbitrary but the same address for each page in the on-chip data-retention RAM area. When this is not executed, data last written may not be written to the on-chip data-retention RAM. If there is a write to the on-chip data-retention RAM after this time, execute this processing after the last write to the on-chip data-retention RAM.
6. Set the STBY and DEEP bits in the STBCR1 register to 1, and then read this register.
7. Read out the DSFR register after clearing the flag in the DSFR register. Then execute the WFI instruction.
8. Set the CPU interface control register (ICCICR) of the interrupt controller to 0 so that an interrupt other than NMI is not notified to the CPU. Then, read the ICCICR register.
9. Execute the WFI instruction.
10. The conflict between the instruction and the NMI interrupt may prevent transition to deep standby mode. After executing the WFI instruction, locate the branch instruction to return to step 9.

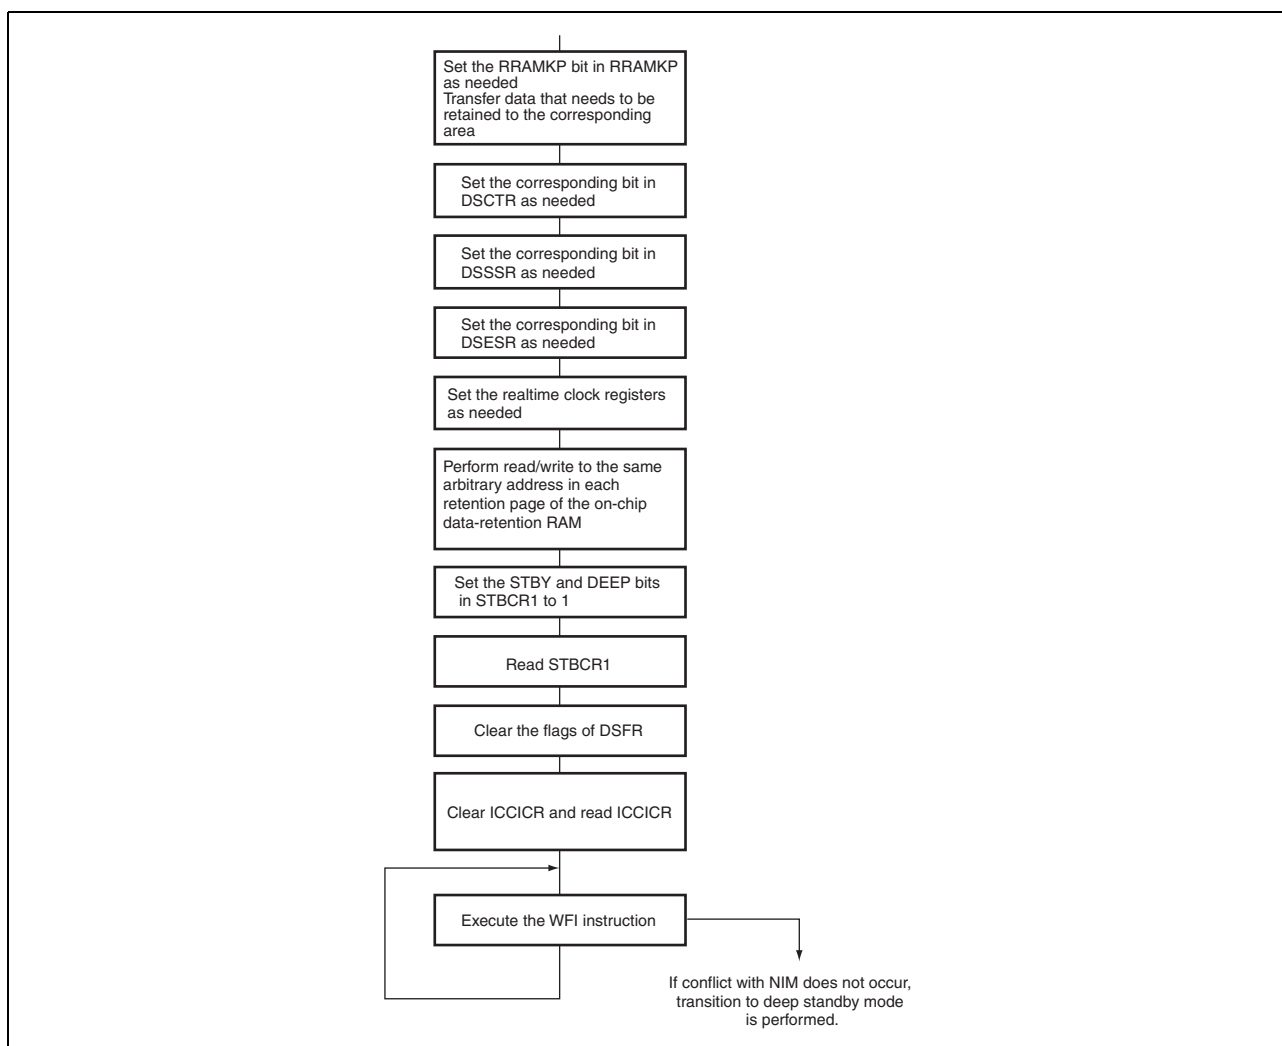

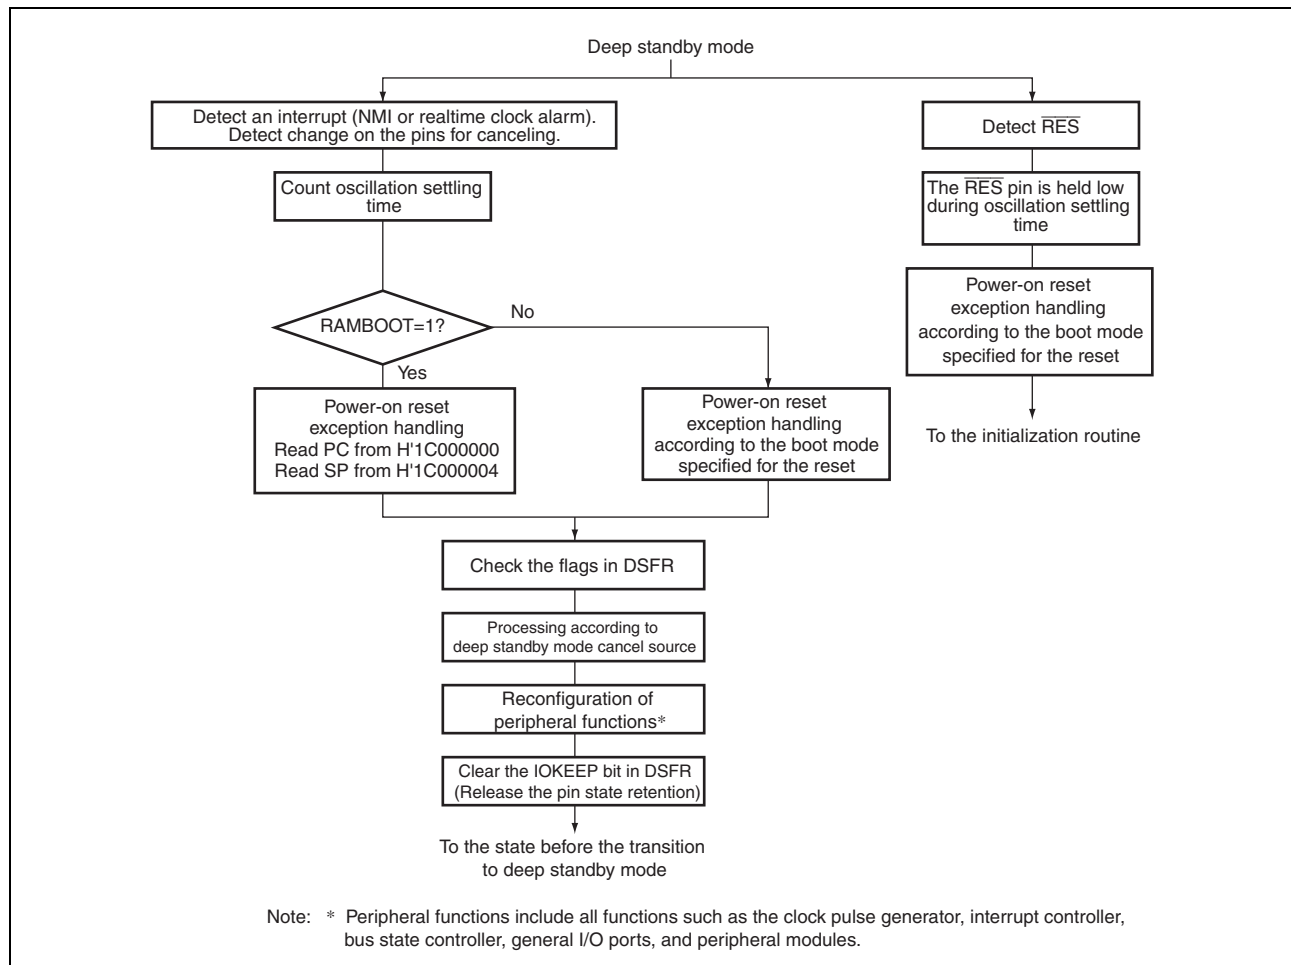

Figure 55.3 Flowchart of Transition to Deep Standby Mode

## (2) Canceling Deep Standby Mode

Deep standby mode is canceled by interrupts (NMI or realtime clock alarm interrupt), change on the pins for canceling, or a reset (power-on reset). The realtime clock alarm interrupt can always cancel deep standby mode regardless of the setting of the running priority register for the interrupt controller. This interrupt can also always cancel this mode do regardless of the states of bit 6 (the FIQ mask bit) and bit 7 (the IRQ mask bit) in the CPSR register of the CPU. When canceling the mode by a source other than a reset, a power-on reset exception handling is executed instead of an interrupt exception handling.

Figure 55.4 shows the flowchart of canceling deep standby mode.

**Figure 55.4** Flowchart of Canceling Deep Standby Mode

- Canceling by a source other than a reset

When the falling or rising edge of the NMI pin (selected by a corresponding bit in DSESR) or falling or rising edge of the pins for canceling (selected by a corresponding bit in DSESR) is detected or the realtime clock alarm interrupt (see section 13.4.4, Alarm Function) is generated, clock oscillation is started after the wait time for the oscillation settling time. After the oscillation settling time has elapsed, deep standby mode is canceled and the power-on reset exception handling is executed.

The clock output phase of the CKIO pin may be unstable immediately after detecting a cancel source and until deep standby mode is canceled.

The detecting of the NMI pin, the pins for canceling, and the realtime clock alarm interrupt becomes enable when the corresponding bits in DSSSR are set. The detected cancel sources are kept, but they are reflected to DSFR after canceling the deep standby mode. When the CPU accepts any interrupts and reads the interrupt response register (ICCIAR), all of the cancel sources that are kept are cleared. When the CPU enters the deep standby mode as the

detected cancel sources are kept, the deep standby mode is canceled immediately after the CPU enters the deep standby mode.

- Canceling with a reset

Driving the RES pin low cancels deep standby mode and causes a transition to the power-on reset state. After this, driving the RES pin high initiates power-on reset exception handling. Output of the internal clock from the CKIO pin also starts by driving the RES pin low.

Keep the RES pin low until the clock oscillation has settled.

### (3) Operation after Canceling Deep Standby Mode

After canceling deep standby mode, the LSI can be activated through the external memory or from the on-chip data-retention RAM, which can be selected by setting the RAMBOOT bit in DSCTR. By setting the EBUSKEEPE bit, the states of the external memory control pins can be retained even after cancellation of deep standby mode. Table 55.3 shows the pin states after cancellation of deep standby mode according to the setting of each bit. Table 55.4 lists the external memory control pins.

**Table 55.3 Pin States after Cancellation of Deep Standby Mode and System Activation Method by the DSCTR Settings**

EBUSKEEPE Bit	RAMBOOT Bit	Activation Method	Pin States After Cancellation of Deep Standby Mode
0	0	External memory	The states of the external memory control pins are not retained. For other pins, the retention of their states is cancelled when the IOKEEP bit is cleared.
0	1	On-chip data-retention RAM	The states of the external memory control pins are not retained. After cancellation of deep standby mode, the retention of the external memory control pin states is cancelled. For other pins, the retention of their states is cancelled when the IOKEEP bit is cleared.
1	0	—	Setting prohibited.
1	1	On-chip data-retention RAM	The states of the external memory control pin are retained. The retention of the states of the external memory control pins and other pins is cancelled when the IOKEEP bit is cleared.

**Table 55.4 External Memory Control Pins in Different Modes**

Boot Mode 0 (CS0 Area: Bus Width: 16 Bits)	Boot Mode 0 (CS0 Area: Bus Width: 32 Bits)	Boot Mode 3 (Serial Flash Boot)	Boot Mode 4 (eSD Boot)	Boot Mode 5 (eMMC Boot)
A[20:1] D[15:0] CS0, RD, CKIO	A[20:2] D[31:0] CS0, RD, CKIO	SPBCLK_0, SPBSSL_0, SPBMO0_0, SPBMO1_0	SD_CLK0, SD_CMD0, SD_D[3:0]0	MMC_CLK, MMC_CMD, MMC_D[3:0]

When deep standby mode is canceled by interrupts (NMI or realtime clock alarm) or changes on the pins for canceling, the deep standby cancel source flag register (DSFR) can be used to confirm which source has canceled the mode. Pins retain the state immediately before the transition to deep standby mode. However, in system activation through the external memory, the retention of the states of the external memory control pins is cancelled so that programs can be fetched after cancellation of deep standby mode. Other pins, after cancellation of deep standby mode, continue to retain the pin states until writing 0 to the IOKEEP bit in DSFR after reading 1 from the same bit. In system activation from the on-chip data-retention RAM, after cancellation of deep standby mode, both the external memory control pins and other pins continues to retain the pin states until writing 0 to the IOKEEP bit in DSFR after reading 1 from the same bit. Reconfiguration of peripheral functions is required to return to the previous state of deep standby mode. Peripheral functions include all functions such as the clock pulse generator, interrupt controller, general I/O ports, and peripheral modules. After the reconfiguration, the retention of the pin state can be canceled and the LSI returns to the state prior to the transition to deep standby mode by reading 1 from the IOKEEP bit in DSFR and then writing 0 to it.

#### (4) Notes on Transition to Deep Standby Mode

If multiple canceling sources have been specified and multiple canceling sources are input, multiple cancel source flags will be set.

### 55.3.5 Module Standby Function

#### (1) Transition to Module Standby Function

The procedure for transitions to the module standby state varies according to whether the STBREQ register has a bit for the corresponding module. Follow the procedures below according to whether this is or is not the case. Disable a module before placing it in the module standby state. In addition, do not access the module's registers while it is in the module standby state.

- (a) Procedure for transition to module standby of modules for which the STBREQ register does not have a corresponding bit

1. Set the MSTP bit of the corresponding module to 1.

- (b) Procedure for transition to module standby of modules for which the STBREQ register has a corresponding bit

1. Set the corresponding bit in the STBREQ register to 1 to generate a request to stop the module.
2. Confirm that the module is ready to be stopped by the corresponding bit in the STBACK register being set to 1.
3. Set the MSTP bit of the corresponding module to 1.

For states of registers in the module standby function, see section 57.3, Register States.

#### (2) Canceling Module Standby Function

Release from the module standby state can be achieved in two ways: starting the module by a power-on reset while the MSTP bit is set to 1, then clearing the MSTP bit to 0, or setting the MSTP bit to 0 to activate the module, setting the MSTP bit to 1 to place the module in the standby state, and then setting the MSTP bit to 0 again. If you use the latter approach, the procedure for release from module standby depends on whether the STBREQ register has a bit for the corresponding module.

- Release from the module standby state after the activation of the module by a power-on reset while the MSTP bit is set to 1

1. Clear the MSTP bit to 0.
2. After that, dummy-read the same register.

- Release from the module standby state after a transition to standby following activation of the module

- (a) Procedure for release from module standby of modules for which the STBREQ register does not have a corresponding bit

1. Clear the MSTP bit to 0, then dummy-read the same register.

- (b) Procedure for release from module standby of modules for which the STBREQ register has a corresponding bit

1. Clear the MSTP bit to 0, then dummy-read the same register.
2. Clear the corresponding bit in the STBREQ register to 0 to cancel the request to stop the module.
3. Confirm that the corresponding bit in the STBACK register has been cleared to 0, indicating the completion of release from standby.

### 55.3.6 Software Reset

Initialization equivalent to a power-on reset is only applied to the selected modules. The procedure for transitions to the software reset state varies according to whether the STBREQ register has a bit for the corresponding module. Follow the procedures below according to whether this is or is not the case.

#### (1) Transition to Software Reset State

- (a) Procedure for transition to the software reset state of modules for which the STBREQ register does not have a corresponding bit

1. Set the SRST bit of the corresponding module to 1.

- (b) Procedure for transition to the software reset state of modules for which the STBREQ register has a corresponding bit

1. Set the corresponding bit in the STBREQ register to 1 to generate a request to stop the module.
2. Confirm that the corresponding bit in the STBREQ register has been set to 1.
3. Set the SRST bit of the corresponding module to 1.

#### (2) Canceling Software Reset

- (a) Procedure for release from the software reset state of modules for which the STBREQ register does not have a corresponding bit

1. Clear the SRST bit of the corresponding module to 0, then dummy-read the same register.

- (b) Procedure for release from the software reset state of modules for which the STBREQ register has a corresponding bit

1. Clear the SRST bit of the corresponding module to 0, then dummy-read the same register.
2. Clear the corresponding bit in the STBREQ register to 0 to cancel the request to stop the module.
3. Confirm that the corresponding bit in the STBACK register has been cleared to 0.

### 55.3.7 Adjustment of XTAL Crystal Oscillator Gain

The gain of the crystal oscillator for XTAL and the realtime clock can be adjusted using the GAIN1 and GAIN0 bits in XTALCTR. To modify the gain of the signal on the EXTAL or XTAL pin, PLL settling time is needed. The settling time is counted using the on-chip watchdog timer. Counting to secure the PLL settling time is not needed when the gain of the signal on the RTC\_X3 or RTC\_X4 pin is changed.

1. The large gain is selected in the initial state.
2. Set the standby\_mode\_en bit of the power control register in the PL310 to 1. For the details of this register, see CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual issued by ARM Ltd.
3. Set the watchdog timer so that the specified settling time should be obtained and stop the watchdog timer. Specifically, the following settings are necessary:  
TME in WTCSR = 0: Stop the watchdog timer.  
CKS[2:0] in WTCSR: Division ratio for watchdog timer count clock  
WTCNT: Initial counter value  
(The watchdog timer starts counting on the set clock.)
4. Set the GAIN0 bit to the desired value.
5. The LSI is internally stopped and the watchdog timer starts counting. The clock is supplied only to the watchdog timer and other internal clocks are stopped. In this state, the CKIO pin continues to output an unstable clock. To avoid malfunction due to the unstable clock, modify the CKOEN2 bit in FRQCR appropriately. Since this state is equivalent to the software standby mode state, some registers of on-chip peripheral modules are initialized. For details, see section 57.3, Register States.
6. When an overflow occurs on the watchdog timer, the specified clock supply is started and the LSI starts operation. The watchdog timer stops after an overflow.

## 55.4 Usage Notes

### 55.4.1 Usage Notes on Setting Registers

When writing to the registers related to power-down modes, note the following.

When writing to the register related to power-down modes, the CPU, after executing a write instruction, executes the next instruction without waiting for the write operation to complete.

Therefore, to reflect the change specified by writing to the register while the next instruction is executed, insert a dummy read of the same register between the register write instruction and the next instruction.

### 55.4.2 Usage Notes when the Realtime Clock is not Used

When the realtime clock is not used, set the MSTP60 bit in STBCR6 to 1 after setting the bits in registers of the realtime clock. For details, see section 55.2.6, Standby Control Register 6 (STBCR6).

- Set the RTCEN bit in the control register 2 (RCR2) to 0
- Set the RCKSEL[1:0] bits in the control register 5 (RCR5) to 00.

## 56.2 Input/Output Pins

Table 56.7 shows the pin configuration of the debugger interface.

**Table 56.7 Pin Configuration**

Name	Pin Name	Input/ Output	Function
Test clock	TCK/SWDCLK	Input	Data is input in serial to this module via the data input pin (TDI) or data is output via the data output pin (TDO) in synchronization with this signal. Functions as the SWDCLK pin in serial wire debug (SWD) mode.
Test mode select	TMS/SWDIO	Input, Input/ Output	Changing this signal in synchronization with the TCK signal determines the state of the TAP controller circuit. Its protocol conforms to the subset of the JTAG standard (IEEE standard 1149.1). Functions as the SWDIO pin in serial wire debug (SWD) mode.
Test reset	$\overline{\text{TRST}}^*$	Input	This signal is received asynchronously with the TCK signal. Asserting this signal resets this module. When power is supplied, this pin should be asserted for a given period regardless of whether or not this module function is used. For details on resetting, see section 56.5.2, Reset Signal Setting.
Test data input	TDI	Input	Data is sent to this module by changing this signal in synchronization with the TCK signal.
Test data output	TDO	Output	Data is read from this module by reading this signal in synchronization with the TCK signal.
Boundary scan setting	BSCANP	Input	Input a high-level signal during boundary-scan testing. Input a low-level signal during normal use.
Clock output	TRACECLK	Output	Trace clock output pin
Enable output	TRACECTL	Output	Trace enable output pin
Data output	TRACEDAT3 to TRACEDATA0	Output	Trace data output pins

Note: \* When designing a board that can use an emulator, the  $\overline{\text{TRST}}$  pin circuit should be designed so that it can be controlled independently and can be set low during the period the  $\overline{\text{RES}}$  pin is asserted low at power-on. When the  $\overline{\text{TRST}}$  pin is not in use, it should be either fixed to low level or connected to the  $\overline{\text{RES}}$  pin (or another pin which operates in the same manner as the  $\overline{\text{RES}}$  pin).

### 56.3 Registers for Boundary-Scan TAP Controller

The boundary-scan TAP controller has the following registers.

**Table 56.8 List of Registers of Boundary-Scan TAP Controller**

Register Name	Abbreviation	R/W	Initial Value	Address	Access Size
Bypass register	BSBPR	—	—	—	—
Instruction register	BSIR	—	H'55	—	—
Boundary scan register	SDBSR	—	—	—	—
ID register	BSID	—	H'08178447	—	—

#### 56.3.1 Bypass Register (BSBPR)

BSBPR is a 1-bit register that cannot be accessed by the CPU. When BSIR is set to BYPASS mode, BSBPR is connected between the TDI and TDO pins. The initial value is undefined.

#### 56.3.2 Instruction Register (BSIR)

BSIR is an 8-bit register. This register is initialized by  $\overline{\text{TRST}}$  assertion or in the TAP test-logic-reset state. BSIR cannot be accessed by the CPU.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	T[7:0]	01010101	—	Test Instruction The instruction of this module is transferred to BSIR through a serial input from the TDI pin. For commands, see Table 56.9.

**Table 56.9 Commands Supported for Boundary Scan TAP Controller**

### 56.3.3 Boundary Scan Register (SDBSR)

SDBSR is a shift register, located on the PAD, for controlling the input/output pins of this LSI. SDBSR cannot be accessed by the CPU. The initial value is undefined. Using the EXTEST, SAMPLE/PRELOAD, CLAMP, and HIGHZ commands, a boundary scan test conforming to the JTAG standard can be carried out. Table 56.10 shows the correspondence between the pins of this LSI and bits of the boundary scan register.

Note 1. The pin names are as listed in the "Port function/dedicated function" column of Table 1.4, List of Pins in section 1.6, List of Pins.

Note 2. Open-drain pin. Setting the data bit for the pin to 0 makes the pin output a low-level signal and setting the data bit for the pin to 1 places the pin in the hi-Z state.

Note 3. Bits of type "control" are active low. When the control bit is at the low level, the corresponding pin becomes an output.

## 56.5 Operation

### 56.5.1 TAP Controller

Figure 56.3 shows the internal states of the TAP controller. State transitions basically conform to the JTAG standard.

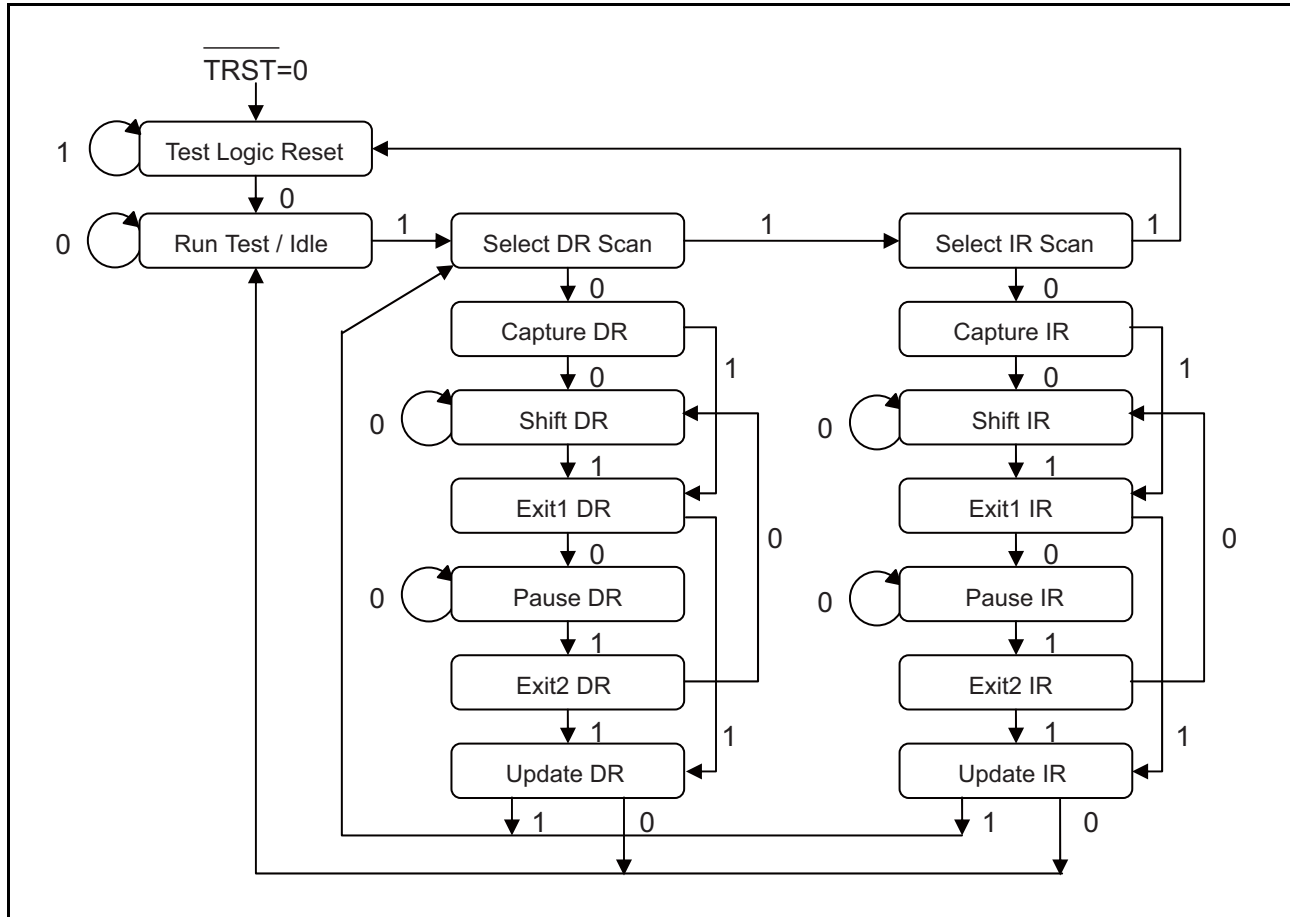

Figure 56.3 State Transitions of TAP Controller

Note: State transition occur according to the TMS value at the rising edge of the TCK signal. The TDI value sampled at the rising edge of the TCK signal and shifted at the falling edge of the TCK signal. TDO value is output at the rising edge of the TCK signal. The TDO signal is in a Hi-Z state for TAP controller states other than Shift-DR and Shift-IR. A transition to the Test-Logic-Reset state by clearing  $\overline{\text{TRST}}$  to 0 is performed asynchronously with the TCK signal.

### 56.5.2 Reset Signal Setting

Table 56.12 Reset Signal Setting

$\overline{\text{RES}}$	$\overline{\text{TRST}}$	Chip State
L	L	The chip is power-on reset and this module is reset.*1
	H	The chip is power-on reset.*1
H	L	This module is only reset.*2
	H	Normal operation*2

Note 1. By asserting the  $\overline{\text{RES}}$  and  $\overline{\text{TRST}}$  signals, the CPU and CoreSight enter the reset state. Set the debugging function while asserting the  $\overline{\text{RES}}$  signal after negating the  $\overline{\text{TRST}}$  signal.

Note 2. When the chip is in CoreSight debugging mode, do not negate the  $\overline{\text{TRST}}$  signal while the  $\overline{\text{RES}}$  signal is at the high-level.

## 56.6 Boundary Scan

Commands can be set in BSIR by this module to place this module's pins in boundary scan mode stipulated by JTAG.

### 56.6.1 Supported Instructions

This LSI supports three mandatory instructions stipulated by JTAG standard (BYPASS, SAMPLE/PRELOAD, and EXTEST) and three option instructions (IDCODE, CLAMP, and HIGHZ).

#### (1) BYPASS

BYPASS is a mandatory instruction that operates the bypass register. This instruction is used to shorten the shift path to speed up serial data transfer involving other LSI on the printed circuit board. This LSI's system circuits are not affected by execution of this instruction.

#### (2) SAMPLE/PRELOAD

SAMPLE/PRELOAD is used to input data from this LSI's internal circuit to the boundary scan register, outputs data from the scan path, and loads data onto the scan path. While this instruction is being executed, signals input to this LSI pins are transmitted directly to the internal circuit, and the values of the internal circuit are directly output externally from the output pins. This LSI's system circuits are not affected by execution of this instruction.

In a SAMPLE operation, a snapshot of a value to be transferred from an input pin to the internal circuit, or a value to be transferred from the internal circuit to an output pin, is latched into the boundary scan register and read from the scan path. Snapshot latching is performed in synchronization with the rising edge of the TCK signal in the Capture-DR state. Snapshot latching does not affect normal operation of this LSI.

In a PRELOAD operation, an initial value is set in the parallel output latch of the boundary scan register from the scan path prior to the EXTEST instruction. Without a PRELOAD operation, when the EXTEST instruction was executed, an undefined value would be output from the output pin until completion of the initial scan sequence (transfer to the output latch) (with the EXTEST instruction, the parallel output latch value is constantly output to the output pin).

#### (3) EXTEST

This instruction is provided to test external circuit when this LSI is mounted on a printed circuit board. When this instruction is executed, output pins are used to output test data (previously set by the SAMPLE/PRELOAD instruction) from the boundary scan register to the printed circuit board, and input pins are used to latch test results into the boundary scan register from the printed circuit board. If testing is carried out by using the EXTEST instruction N times, the Nth test data is scanned-in when test data (N-1) is scanned out. The data loaded into the output pin boundary scan register in the Capture-DR state are not used for external circuit testing (data are replaced by the shift operation).

#### (4) IDCODE

Commands can be set in BSIR via pins of this module to place the module's pins in the IDCODE mode stipulated by JTAG. When this module is initialized ( $\overline{\text{TRST}}$  is asserted or TAP is in the Test-Logic-Reset state), the IDCODE mode is entered.

#### (5) CLAMP, HIGHZ

Commands can be set in BSIR via pins of this module to place the module's pins in the CLAMP or HIGHZ mode stipulated by JTAG.

### 56.6.2 Points for Attention

1. Boundary scan mode does not cover clock-related signals (EXTAL, XTAL, CKIO, AUDIO\_X1, AUDIO\_X2, USB\_X1, USB\_X2, RTC\_X1, and RTC\_X2).
2. Boundary scan mode does not cover reset-related signal ( $\overline{\text{RES}}$ ).
3. Boundary scan mode does not cover this module's signals (TCK, TDI, TDO, TMS,  $\overline{\text{TRST}}$ , and BSCANP).
4. Boundary scan mode does not cover USB-related signals (DP0, DP1, DM0, DM1, VBUS0, VBUS1, and REFRIN).
5. Boundary scan mode does not cover P0\_3.
6. Boundary scan mode does not cover the digital video decoder related signals (VIN1A, VIN2A, VIN1B, VIN2B, VIDEO\_X1, VIDEO\_X2, VRP, VRM, and REXT).
7. Boundary scan mode does not cover AVref (reference voltage pin for the A/D converter).

### 56.7 Usage Notes

1. Once a command of this module is set, it will not be modified unless another command is reissued. If the same command is given continuously, the command must be set after a command (BYPASS, etc.) that does not affect LSI operations is once set.
2. Regardless of whether or not this module is to be used, it should be initialized by asserting the  $\overline{\text{TRST}}$  signal when power is supplied and on release from deep standby mode (excluding fake debug mode) through assertion of the  $\overline{\text{RES}}$  signal.
3. Be sure to wait for at least 200 ns after negating the  $\overline{\text{TRST}}$  signal before starting TAP controller operation.
4. Be sure to fix the TMS pin to the high level until 200 ns have elapsed after negation of the  $\overline{\text{TRST}}$  signal.

Note 3. Counting up continues.

Note 4. Transfer can proceed.

Note 5. The value of RTCEN bit is retained.

Note 6. The GAIN0 bit is initialized when the realtime clock is not using the EXTAL pin. The GAIN1 bit is initialized when the realtime clock is not using the RTC\_X1 or RTC\_X3 pin.

Note 7. Initialized on assertion of  $\overline{\text{TRST}}$  or when the TAP controller is placed in Test-Logic-Reset state.

Note 8. Access to these registers from the I/O area (SLV6) is not possible while TRST is asserted.

Note 9. Initialized on assertion of  $\overline{\text{TRST}}$ .

Note 10. Retained in FAKE debug mode.

## 58. Electrical Characteristics

### 58.1 Absolute Maximum Ratings

**Table 58.1 Absolute Maximum Ratings**

Item	Symbol	Value	Unit	
Power supply voltage (I/O)	PV <sub>CC</sub>	-0.3 to 4.2	V	
Power supply voltage (Internal)	V <sub>CC</sub>	-0.3 to 1.6	V	
PLL power supply voltage	PLL <sub>VCC</sub>	-0.3 to 1.6	V	
Analog power supply voltage	AV <sub>CC</sub>	-0.3 to 4.2	V	
Analog reference voltage	AV <sub>ref</sub>	-0.3 to AV <sub>CC</sub> +0.3	V	
USB transceiver analog power supply voltage (I/O)	USBAP <sub>VCC</sub>	-0.3 to 4.2	V	
USB transceiver digital power supply voltage (I/O) Note: Products in BGA packages do not have this pin.	USBDP <sub>VCC</sub>	-0.3 to 4.2	V	
USB transceiver analog power supply voltage (internal)	USBA <sub>VCC</sub>	-0.3 to 1.6	V	
USB transceiver digital power supply voltage (internal) Note: Products in BGA packages do not have this pin.	USBD <sub>VCC</sub>	-0.3 to 1.6	V	
Power supply for USB 480 MHz (internal) Note: Products in BGA packages do not have this pin.	USB <sub>UVCC</sub>	-0.3 to 1.6	V	
A/D converter power supply voltage for video signal input	VDA <sub>VCC</sub>	-0.3 to 4.2	V	
LVDS analog power supply voltage	LVDSAP <sub>VCC</sub>	-0.3 to 4.2	V	
LVDS PLL power supply voltage	LVDSPLL <sub>VCC</sub>	-0.3 to 1.6	V	
Input voltage	VBUS	V <sub>in</sub>	-0.3 to 5.5	V
	Other input pins	V <sub>in</sub>	-0.3- to 3.3-V power supply (PV <sub>CC</sub> , AV <sub>CC</sub> , USBAP <sub>VCC</sub> , USBDP <sub>VCC</sub> , VDA <sub>VCC</sub> , LVDSAP <sub>VCC</sub> ) +0.3	V
Operating temperature	Ambient temperature	T <sub>a</sub>	-40 to +85	°C
	Junction temperature	T <sub>j</sub>	-40 to +125	°C
Storage temperature	T <sub>stg</sub>	-55 to +125	°C	

Caution: Permanent damage to the LSI may result if absolute maximum ratings are exceeded.

### 58.2 Power-On/Power-Off Sequence

The 1.2-V power supply (V<sub>CC</sub>, PLL<sub>VCC</sub>, USBA<sub>VCC</sub>, USBD<sub>VCC</sub>, USB<sub>UVCC</sub>, and LVDSPLL<sub>VCC</sub>) and 3.3-V power supply (PV<sub>CC</sub>, AV<sub>CC</sub>, USBAP<sub>VCC</sub>, USBDP<sub>VCC</sub>, VDA<sub>VCC</sub>, and LVDSAP<sub>VCC</sub>) can be turned on and off in any order.

When turning on the power, be sure to drive both the  $\overline{\text{TRST}}$  and  $\overline{\text{RES}}$  pins low; otherwise, the output pins and input/output pins output undefined levels, resulting in system malfunction.

When turning off the power, drive the  $\overline{\text{TRST}}$  and  $\overline{\text{RES}}$  pins low if the undefined output may cause a problem.

Note 1. The maximum value (fmax) of CKIO (external bus clock) depends on the number of wait cycles and the system configuration of your board.

Note 2. 1/2 t<sub>cyc</sub> indicated in minimum and maximum values for the item of delay, setup, and hold times represents a half cycle from the rising edge with a clock. That is, 1/2 t<sub>cyc</sub> describes a reference of the falling edge with a clock.

Setup time for start/restart condition	t <sub>SU:STA</sub>	I/O	4.7	-	0.6	-	μs
Data hold time (I <sup>2</sup> C bus device)	t <sub>HD:DAT</sub>	I/O	0*2	-	0*2	-	μs

Pulse width of spikes that must be suppressed by the input filter	t <sub>SP</sub>	Input	-	-	0	50*5	ns

In the above table and subsequently, SCL and SDA refer to the RIICnSCL and RIICnSDA signals, respectively.

Note 1. The first clock pulse is generated on the SCL line after the start condition has been issued and the hold time has elapsed.

Note 2. This module requires a minimum of 300 ns hold time internally for the SDA signal to handle the period over which the falling edge of SCL has not reached a defined level (time until the CnSCL signal reaches V<sub>IL</sub> (max.) from V<sub>IH</sub> (min.)).

Note 3. The fast-mode I<sup>2</sup>C bus device can be used in the standard mode I<sup>2</sup>C bus system. In this case, the minimum value of the data setup time (t<sub>SU:DAT</sub> (min.) 250 [ns]) must be satisfied.

If the system does not extend the low period of SCL clock (t<sub>LOW</sub>), this condition is automatically satisfied. If the system extends the low period of SCL clock (t<sub>LOW</sub>), transmit the subsequent data bit to the SDA line before the SCL line is released (t<sub>R</sub> (max.) + t<sub>SU:DAT</sub> (min.) = 1000 + 250 = 1250 [ns]; (standard mode I<sup>2</sup>C bus specification)).

Note 4. Total capacitance of one bus line. The allowable maximum bus capacitance may differ from this specification, depending on the actual operating voltage and frequency of an application. For techniques to cope with a large bus capacitance, see the I<sup>2</sup>C bus specification provided by NXP Semiconductors.

Note 5. Noise is removed by the analog and digital input filters. The level of noise reduction of the digital input filter is determined by the period of internal reference clock (IICφ) and the NF[1:0] bits in RIICnMR3. For details, refer to section 18, I<sup>2</sup>C Bus Interface.

## [Legend]

I:	Input
O:	Output
H:	High-level output
L:	Low-level output
Z:	High-impedance

- Note 1. Indicates the power-on reset by low-level input to the  $\overline{\text{RES}}$  pin. The pin states after a power-on reset by the watchdog timer overflow is the same as the initial pin states at normal operation (see section 54, Ports).
- Note 2. After the chip has been released from deep standby mode by the input on pins for canceling the standby mode such as NMI, the pins retain the state until the IOKEEP bit in the deep standby cancel source flag register (DSFR) is cleared (see section 55, Power-Down Modes).
- Note 3. The EBUSKEEPE bit in deep standby control register (DSTCR) (see section 55, Power-Down Modes).
- Note 4. This LSI enters the power-on reset state for a certain period after recovery from deep standby control mode (see section 55, Power-Down Modes).
- Note 5. Depends on the setting of the RCKSEL bit in the realtime clock control register 5 (RCR5) (see section 13, Realtime Clock).
- Note 6. When pins for the connection with a crystal resonator are not used, the input pins (EXTAL, RTC\_X1, RTC\_X3, AUDIO\_X1, USB\_X1, and VIDEO\_X1) must be fixed (pull-up/down resistor, power supply, or ground.) and the output pins (XTAL, RTC\_X2, RTC\_X4, AUDIO\_X2, USB\_X2, and VIDEO\_X2) must be open.
- Note 7. Depends on the setting of the CKOEN bit in the frequency control register (FRQCR) of the clock pulse generator (see section 6, Clock Pulse Generator).
- Note 8. Depends on the setting of the PIPCnm bit in the port IP control register (PIPCn) of the general I/O ports.
- Note 9. Depends on the setting of the HIZ bit in the standby control register 2 (STBCR2) (see section 55, Power-Down Modes).
- Note 10. Depends on the setting of the HIZMEM bit in the common control register (CMNCR) of the bus state controller (see section 8, Bus State Controller).
- Note 11. Depends on the setting of the HIZCNT bit in the common control register (CMNCR) of the bus state controller (see section 8, Bus State Controller).
- Note 12. Depends on the setting of the corresponding bit in the deep standby cancel source select register (DSSSR) and the RCKSEL bit in the realtime clock control register 5 (RCR5) (see section 55, Power-Down Modes).
- Note 13. Depends on the setting of the RTCEN bit in the realtime clock control register 2 (RCR2) and the RCKSEL bit in the realtime clock control register 5 (RCR5) (see section 13, Realtime Clock).
- Note 14. Z when the TAP controller is neither the Shift-DR nor Shift-IR state.
- Note 15. When this is an output, the output is fixed to either the High or Low level. There is no oscillation.

### 59.4 Recommended Combination of Bypass Capacitor

Mount a multilayer ceramic capacitor between a pair of the power supply pins as a bypass capacitor. These capacitors must be placed as close as the power supply pins of the LSI. The capacitance of the capacitors should be used 0.1  $\mu\text{F}$  to 0.33  $\mu\text{F}$  (recommended values). For details of the capacitor related to the crystal resonator, see section 6, Clock Pulse Generator.

Figure 59.1 is an example of the externally allocated capacitor in the products in 256-pin QFP packages.

## B. Thermal Characteristics

The junction temperature ( $T_j$ ) of an average sample (typ. value) can be calculated from either of the following expressions.

Calculation by using  $\theta_{ja}$

$T_j = T_a + (P_D \times \theta_{ja})$ , where

- $T_j$ : junction temperature;
- $T_a$ : ambient temperature;
- $P_D$ : power consumption of the entire LSI; and
- $\theta_{ja}$ : thermal resistance between  $T_j$  and  $T_a$ .

Calculation by using  $\Psi_{jt}$

$T_j = T_t + (P_D \times \Psi_{jt})$ , where

- $T_t$ : temperature at the center of the top of the package; and
- $\Psi_{jt}$ : thermal characteristics parameter representing the difference between  $T_j$  and  $T_t$ .

Since the value of  $\theta_{ja}$  varies greatly with the usage environment (e.g. the board and casing), the junction temperature ( $T_j$ ) calculated by using  $\theta_{ja}$  is less accurate. Accordingly, when calculating  $T_j$  by using  $\theta_{ja}$ , allow a sufficient margin in designing the system. The value of  $\Psi_{jt}$  varies little with differences in the usage environment, but pay particular attention to measuring the temperature at the center of the top of the package ( $T_t$ ) if you use this approach. For the values of  $\theta_{ja}$  and  $\Psi_{jt}$ , contact your local sales representative.
